Purpose

Start regional fragmentation studies

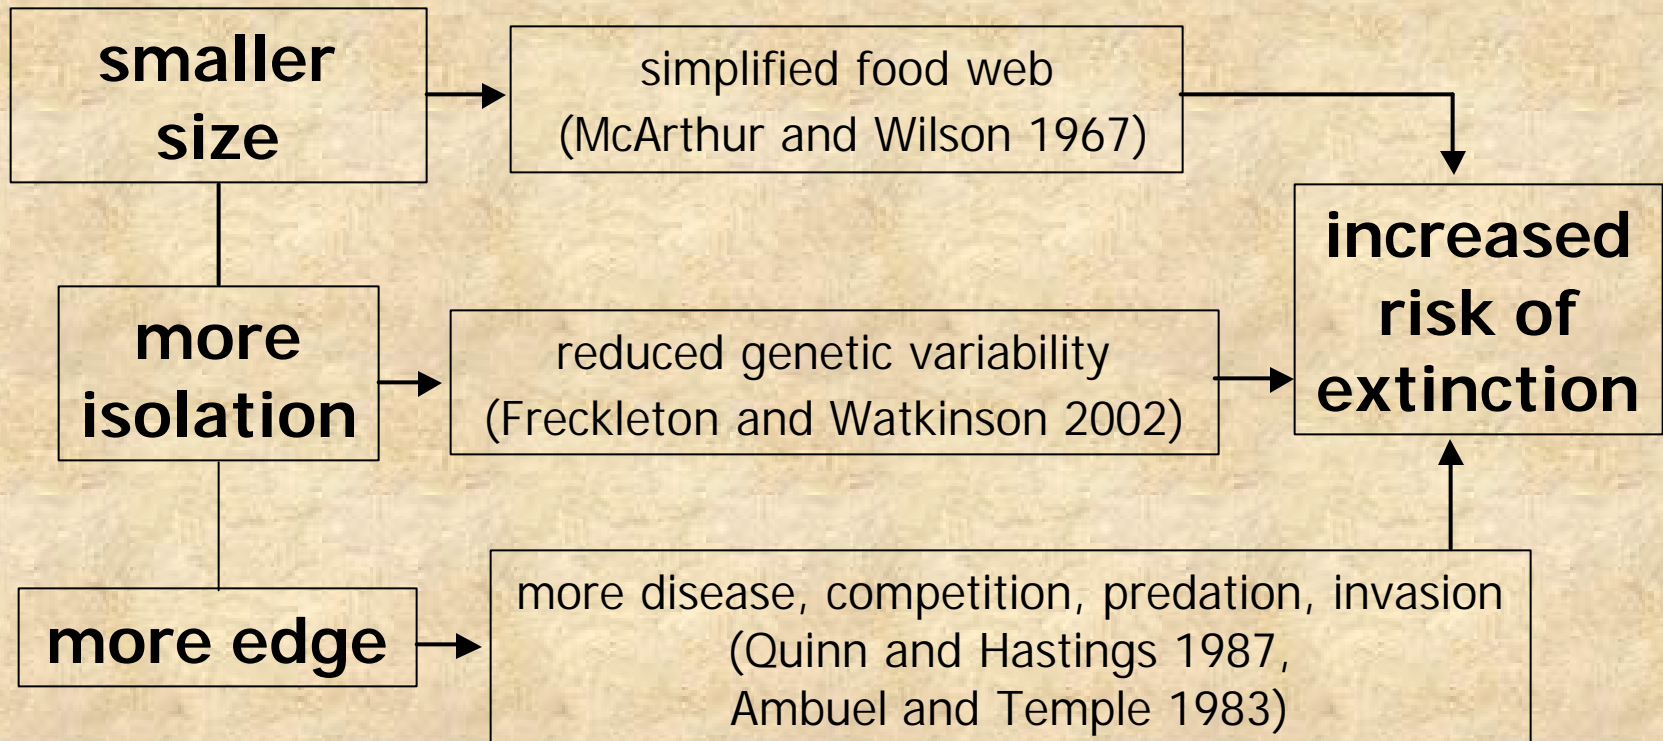

- Illustrate the scale-dependency of fragmentation analysis
- Develop hypotheses of habitat fragmentation that can be genetically tested at the landscape scale

An aerial photograph of a landscape showing a river winding through a patchwork of agricultural fields and some trees. The top half of the image is a dark, semi-transparent banner containing the title text.

Fragmentation Definition

Reduction in size and increase in separation between areas of like habitat, often with changes in patch shape.

Conceptual Model

Steps in Fragmentation Analyses

Species-specific, so *need to select species and develop their rule sets.*

Focus on Patch *Type 1*

resident rails rule set

- ✓ Upland areas > 200 ft wide
- ✓ Open water areas > 200 ft wide at low tide
- ✓ Tidal channels > 200 ft wide from bank-top to bank-top.
- ✓ Man-made levees on 1:24k scale USGS maps
- ✓ Paved Roads of any size

Distribution of Patch Type 1

Historical
Distribution
of
Tidal Marsh
(pre Euro-American
contact)

Distribution of Patch Type 1

Map of the
historical Type 1
patches

313 patches total

Distribution of Patch Type 1

Map of the
modern Type 1
patches

412 patches total

Distribution of Patch Size

Distribution of Type 1 Patch Size

Distribution of Patch Size

Small patches were historically abundant.

Historical small patches are gone; most small patches are relics of large patches.

Maximum patch size has been cut in half.

Distance between Patches

Distance between Patches

The frequency of close patches has increased 50%.

The frequency of moderately close patches has increased 200%.

The frequency of far apart patches has increased 100%.

Patch Type 1 Isolation

Patch Type 1 Isolation

The frequency of minor isolation has not changed.

The frequency of moderate isolation has increased 50-75%.

The frequency of major isolation has increased 25%.

Patch Size and Isolation

Isolation Index Related to Patch Size

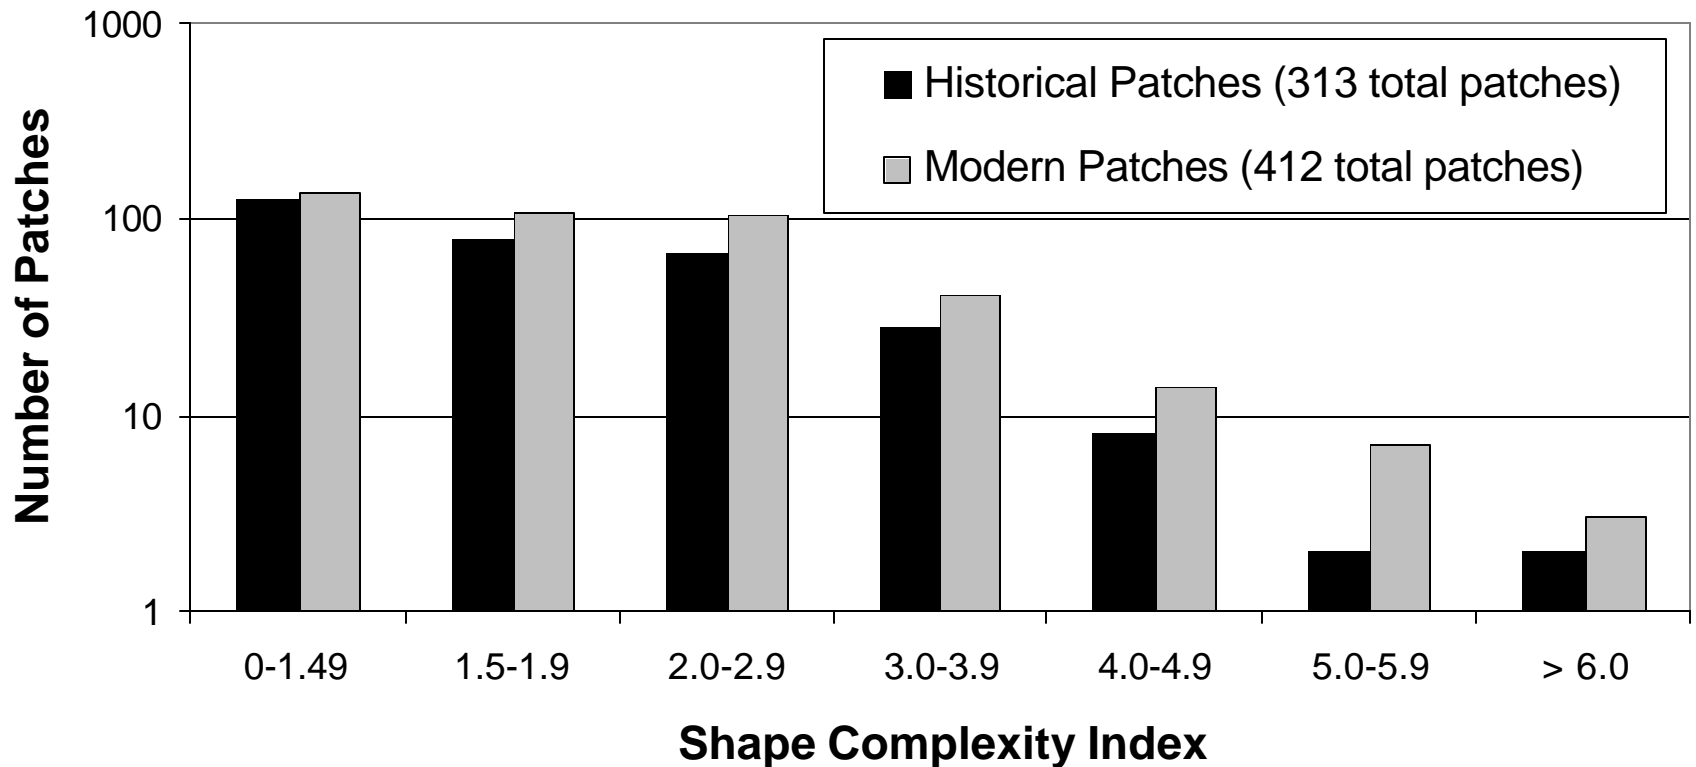

An aerial photograph of a landscape featuring a winding river or stream, surrounded by green fields and some distant trees. The image is used as a background for the title.

Patch Size and Isolation

Isolation is not related to patch size.

Patch Shape

Distribution of Type 1 Patch Shape Complexity

Patch Shape

Shape complexity (perimeter:area) has generally increased.

The frequency of moderate complexity has increased about 75%.

The frequency of very complex patches has increased 100-200%.

Patch Shape

Shape Complexity Related to Patch Size

Patch Shape

Patch shape complexity increases with patch size.

Historical Patch Shape

Wide patches
exist between
uplands and
open water

Modern Patch Shape

Narrow
patches exist
between
uplands and
levees

Observations about Fragmentation

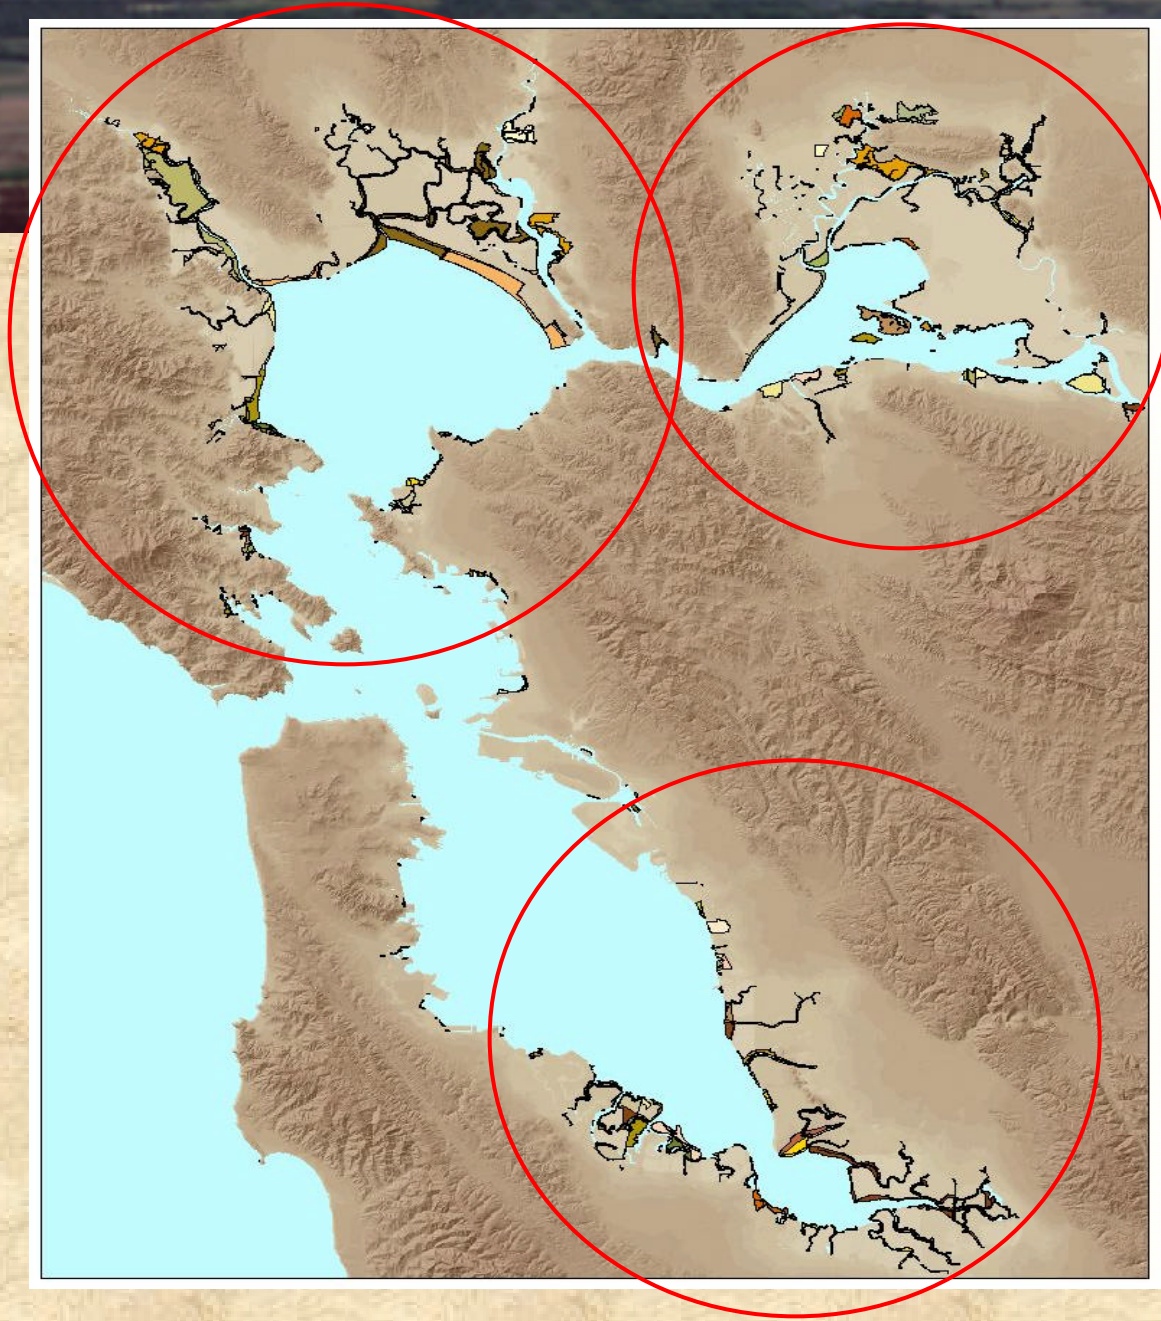

- Small patches were historically abundant.
- Maximum patch size has decreased.
- Proportion of small patches has increased.
- Complexity of patch shape has increased.
- Shape complexity increases with patch size.
- Isolation has increased for all patches sizes.

Emerging View

For rails and turtles, historical habitat array featured 3 areas of very large adjacent patches and many small patches between.

Emerging View

In the modern habitat array, the 3 areas are smaller, further apart, have fewer large patches, and fewer patches between.

Part 2: Cross-scale Exploration of Stressor-State Correlations

Cross-scale Stressor Analysis

Five transects to characterize the drainage system plant community of each EMAP Core Station

An aerial photograph showing a wide river with a reddish-brown hue, likely due to sediment, flowing through a landscape of green marshland and some distant buildings.

Cross-scale Stressor Analysis

Stressors at Scales of Watersheds and Marsh Buffers

Landcover

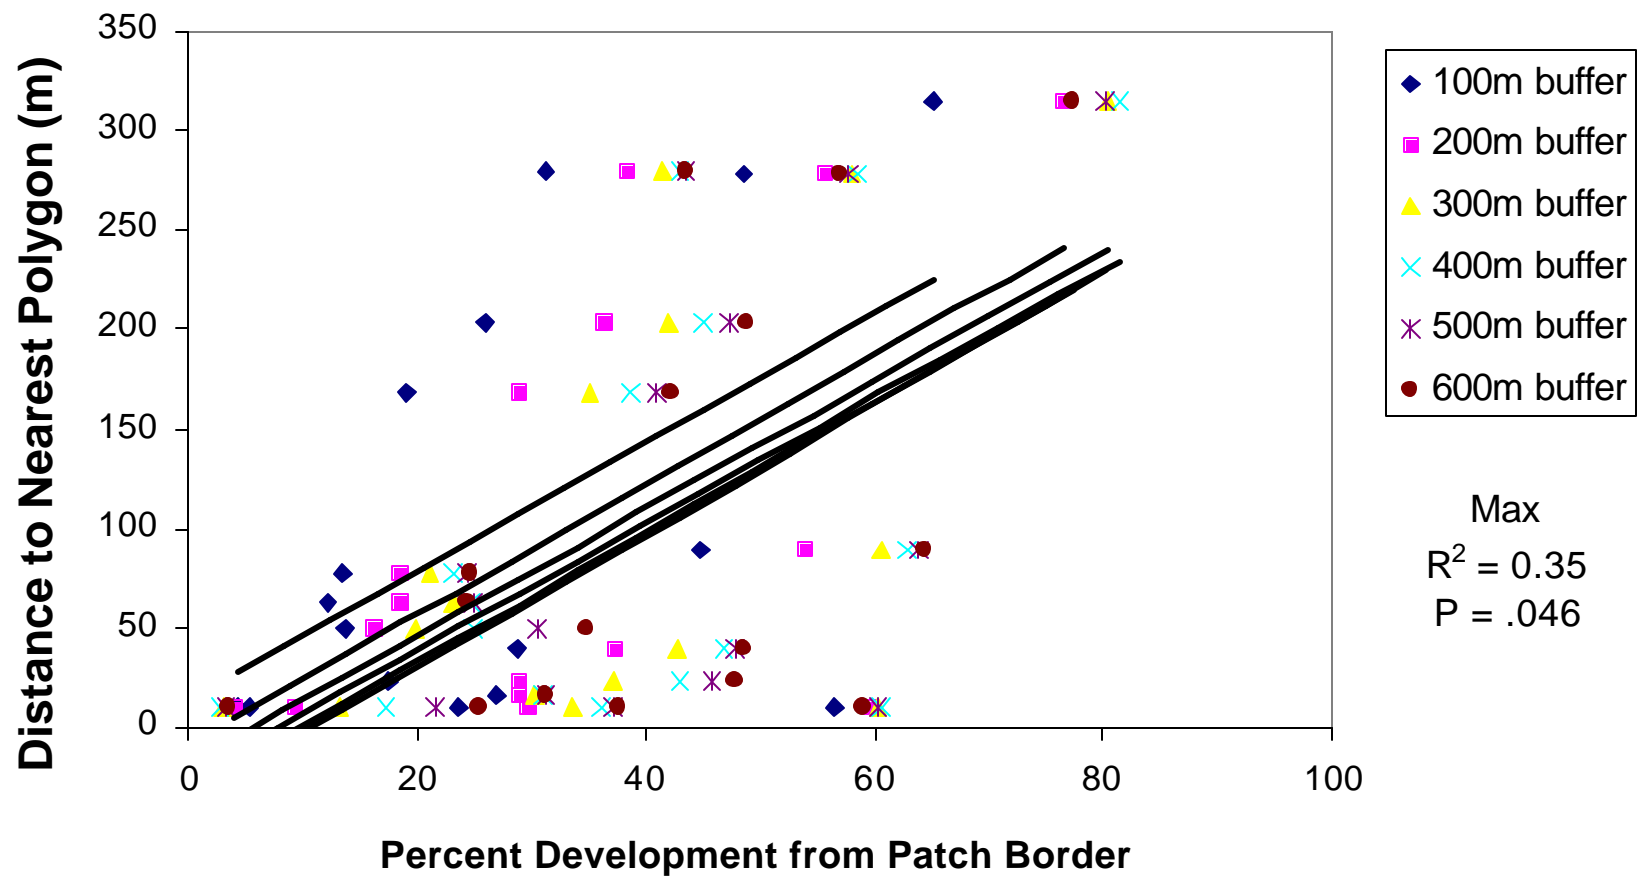

Human Demographics

Patch Shape (perimeter:area)

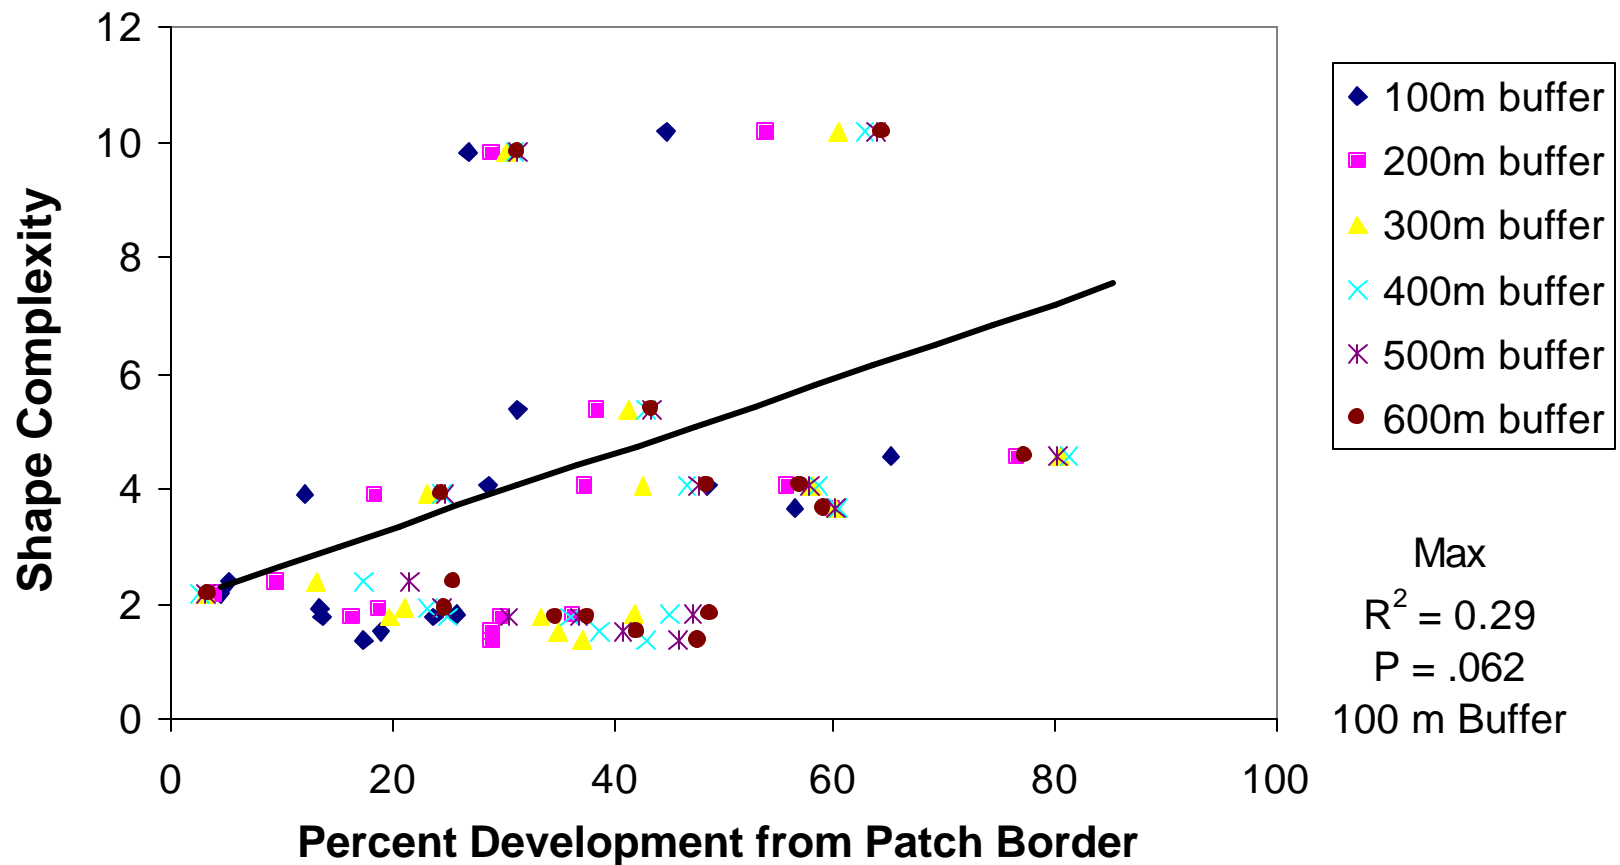

Patch Isolation Relates to Whole Watershed Development

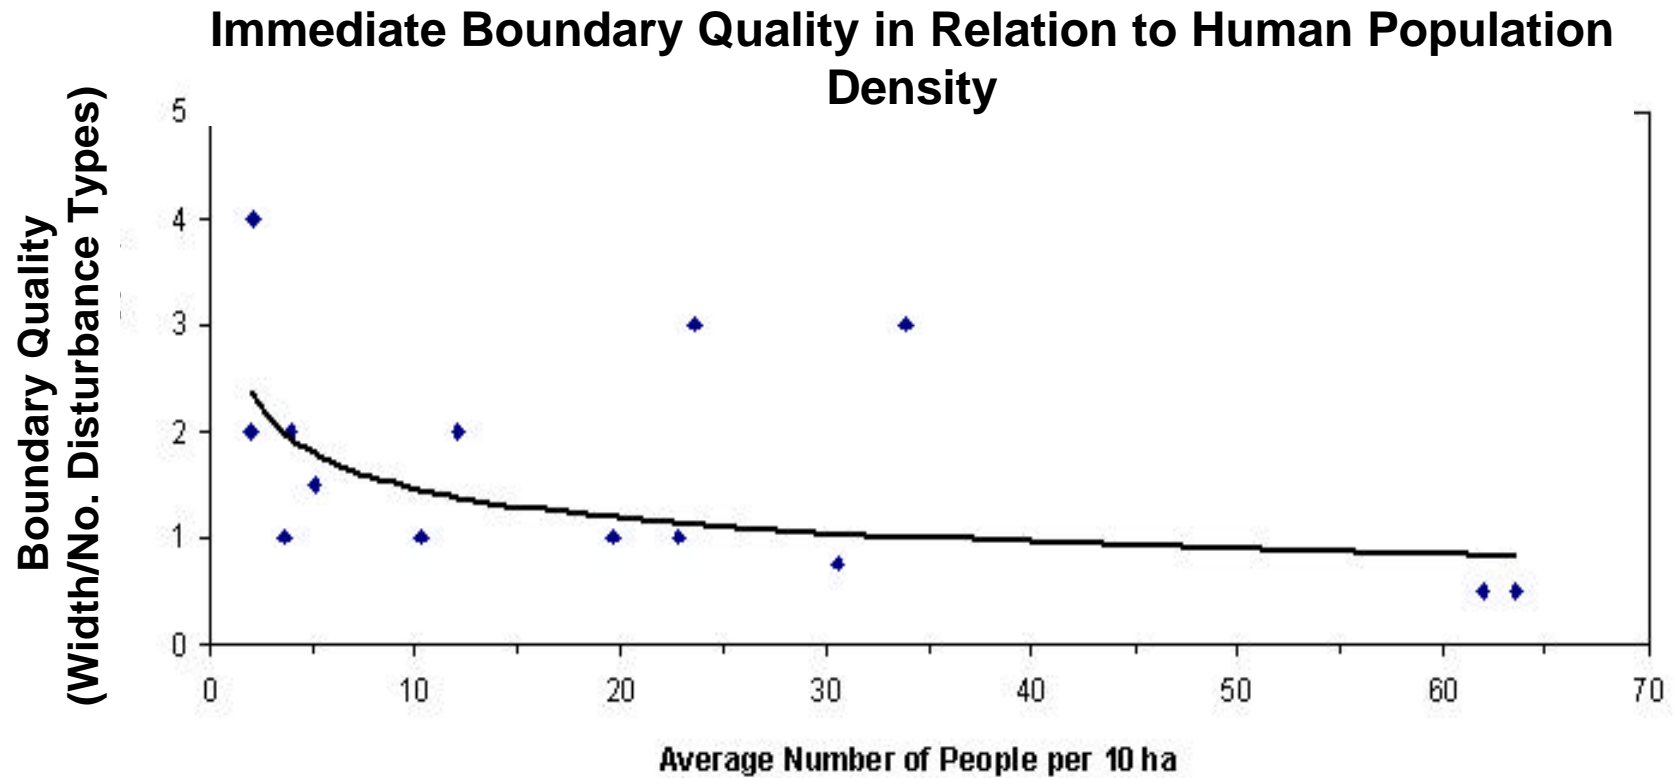

Inter-patch Distance Relates to Buffer Development

Patch Shape Relates to Buffer Development

Quality of Patch Boundary Relates to Number of People in Watershed

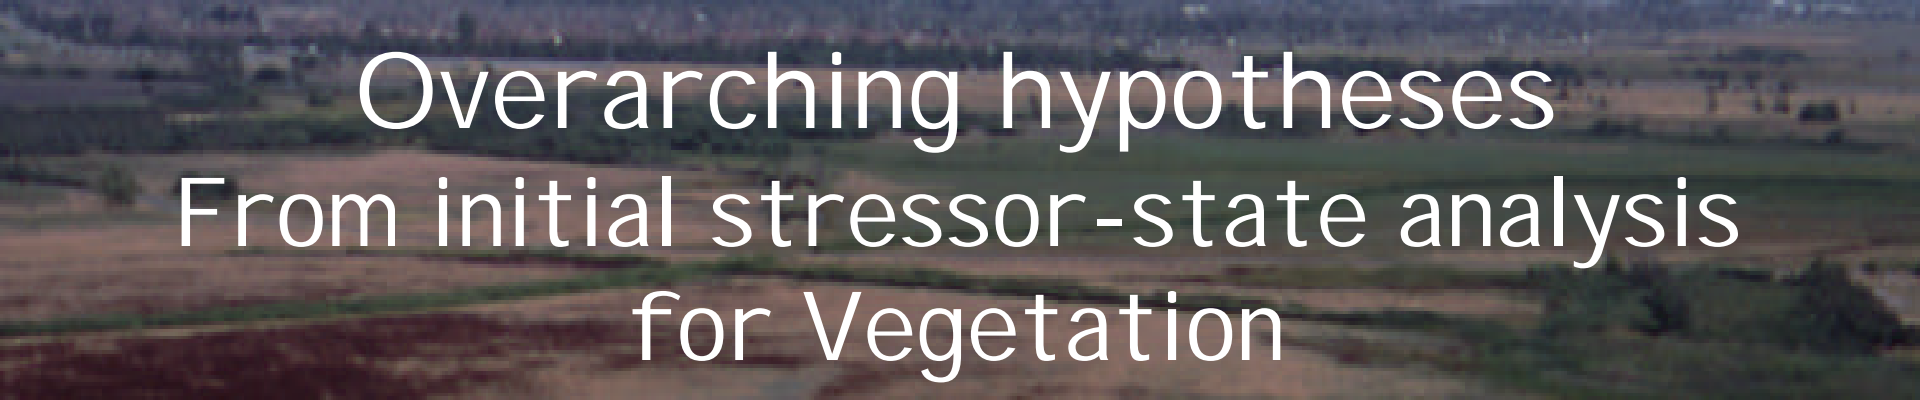

Drainage System Plant Species Richness Relates to Patch Shape

Drainage System Plant Community Integrity Relates to Patch Shape

**Shape Complexity Related to
Native Plant Species Coverage of Transects**

Overarching hypotheses

From initial stressor-state analysis for Vegetation

Watershed development has led to unnaturally complex tidal marsh shapes ... with an overabundance of upland edge ... that tends to be disturbed by adjacent land uses ... resulting in local decreases in plant community integrity.

Thank You
