US ERA ARCHIVE DOCUMENT

SOUTHEAST ALASKA TRIBAL TOXINS

A Partnership to Monitor Harmful Algal Blooms

Projects and Programs

- Southeast Alaska Tribal Toxins (SEATT)
- Southeast Alaska Regional Ocean Acidification Monitoring (SEAROAM)
- Sitka Tribe of Alaska Environmental Research Lab (STAERL)
- Integrated Alexandrium Cyst bed Mapping in Southeast Alaska (IACSEA)

WHY DO WE NEED SEATOR

- Support SE partnered Tribes working on climate change related impacts on the marine environment
- Outreach, community access to data, training
- UNIFIED CREDIBILITY

WHY A PARTNERSHIP?

A *Common Concern* about subsistence clam resources

No assistance from AK state agencies

STA reached out to SE Tribes

EPA IGAP funds for baseline phytoplankton

Create an early warning system

South East Alaska Tribal Toxins
November 2013

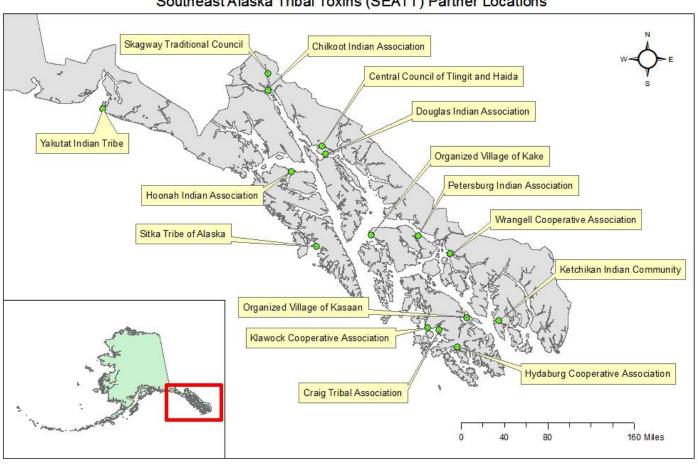

SOUTHEAST TRIBAL PARTNERS

Southeast Alaska Tribal Toxins (SEATT) Partner Locations

Who Regulates for PSP and toxins in Alaska?

 Alaska Department of Environmental Conservation follows FDA regulations for all commercially harvested shellfish in Alaska under the National Shellfish Sanitation Program

What about subsistence users?

 Alaska has no long-term SUBSISTENCE OR RECREATIONAL regulatory testing.

What does monitoring look like?

Equipment and Training

Equipment

- Digital Microscope with Camera
- Refractometer and Thermometer
- Phytoplankton Net
- Filtering apparatus
- Identification tools

Training

- Workshops in Sitka
- Sampling Manual
- Videos
- Site Visits

Updates to www.seator.org

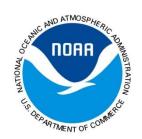

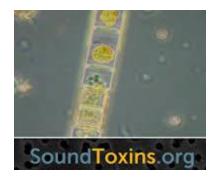

- SoundToxin Database and Phytoplankton Monitoring Network (NOAA)
 - National database for all monitoring groups
 - Used by researchers, shellfish growers, and resource managers for early

warning system

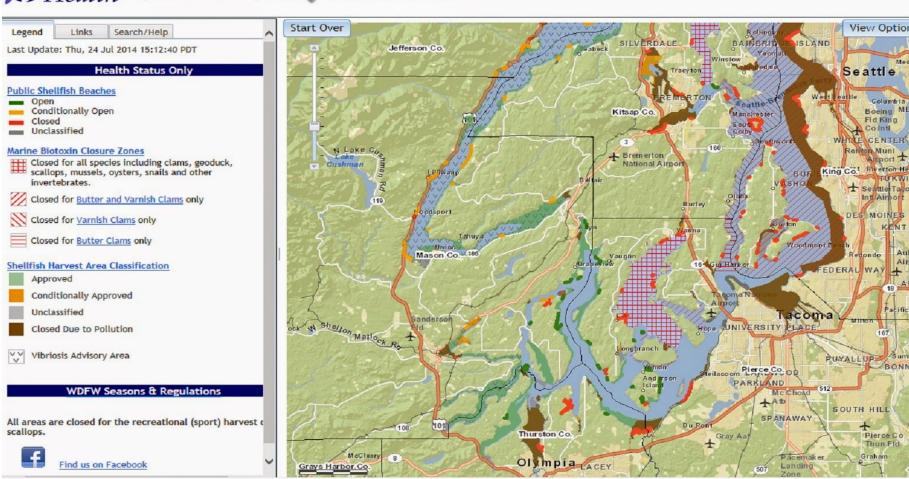

Interactive Mapping Tool

Health Shellfish Safety Information

Sitka Tribe of Alaska Environmental Regulatory Lab (STAERL)

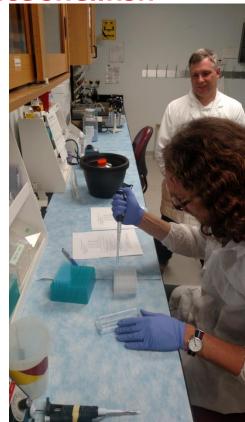

Developed to support SE Tribes (SEATT) with shellfish toxin analysis.

Tribes can use STAERL to develop subsistence shellfish

management plans

RBA: receptor binding assay

- Provide STX data (OMA 2011.27)
- Lower detection limit
 (6.4 μg/100g)
- High throughput
 - Screen 23 samples/plate
- Research other species to amend AOAC

ELISA: enzymed linked imunoabsorbant assay

Domoic Acid (OMA 2006.02)

Outreach and community

Local subsistence harvesters can utilize Lab

Toxic Shellfish 101 How plankton can ruin your dinner plans

Step 1: Phytoplankton "Bloom"

When conditions are just right, one species or genus of plankton can multiply especially rapidly. If the plankton is toxin-producing, toxin levels can rapidly increase with the populations. The exact factors that lead to algal blooms and to toxin production are still not well-known.

Step 2: Shellfish Pick Up Toxins

Shellfish like clams, mussels, and scallops eat plankton that they filter out of the water. During a harmful bloom, a shellfish's daily meal is almost entirely made of toxic plankton. Since a single shellfish can filter up to 20 gallons of water a day, even low toxin levels can become highly concentrated. Most shellfish are unaffected by planktonic toxins and continue feeding as usual throughout the bloom.

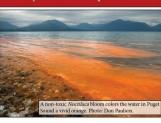

Step 3: Shellfish Are Eaten

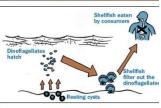

There is no visual way to tell if a shellfish is safe or not. The water can be clear or colored, the shellfish can be eaten or shunned by local wildlife, the time since the last bloom could be recent or extensive, but it would still be impossible to say whether wild shellfish were safe to harvest. As a result, people are hospitalized every year in Alaska after eating unsafe shellfish.

Getting sick could require as many as thirty shellfish or as few as one and could take only minutes or up to 48 hours depending on the toxin type and the amount present.

Step 4: The Threat Dissipates

After as little as a few days or as long as a few months, the bloom fades away. As shellfish stop eating toxic food, their toxin levels also decrease. Some species like blue mussels clear their toxins relatively quickly, while others, like butter clams, can take months to return to safe levels.

Which Animals Should You Be Most Concerned About?

Filter feeding bivalves are especially prone to accumulating dangerous levels of toxin. These include mussels, clams, oysters, and scallops. Carnivorous scavengers like crabs can pick up toxins in their viscera (the crabs "butter") from eating contaminated shellfish. Plankton-eating forage fish like herring and sand lance are also susceptible to planktonic toxins.

Since chitons, limpets, and sea urchins are primarily herbivorous, they are generally not at risk for accumulating planktonic toxins.

Get your shellfish tested! Contact STA's Environmental Lab for testing information and protocols. 907-747-7356 Email: seator@sitkatribe-nsn.gov

Harmful Alaskan Algal Species

llexandrium spp

- TOXIC. Alexandrium species can produce saxitoxins that accumulate in shellfish. These toxins cause Paralytic Shellfish Poisoning and cannot be neutralized by freezing or cooking.
- Alexandrium causes commercial shellfishery closures almost every year. Recreational shellfish harvesters are also sickened every year.
- Alexandrium has a cyst phase that allows cells to remain dormant for long periods of time (even years!). Cysts are also toxic and can contaminate shellfish.
- Some Alexandrium species can create a reddish tinge in the water, hence the name "red tide". Many blooms are not visible, however.
- Blooms of Alexandrium do not have consistent triggers, but they tend to be most common in mid-summer, after large rain events, or after a cyst bed has been disturbed.

Prior Assecuted Prior

Pseudo-nitzschia spp.

- TOXIC. Pseudo-nitzschia species can release domoic acid. Like saxitoxins, domoic acid accumulates in shellfish and cannot be neutralized by freezing or cooking. Domoic acid can lead to Amnesic Shellfish Poisoning.
- In July 2015, a Pseudo-nitzschia bloom stretched from southern California into Southeast Alaska. The southern portion of this bloom produced enough domoic acid to shut down shellfisheries along the coast and to sicken hundreds of sea lions.
- Colorless! Blooms of Pseudo-nitzschia are not visible without a microscope.
 Pseudo-nitzschia is one of the earliest harmful algal species to bloom
- Pseudo-nitzschia is one of the earliest harmful algal species to bloom in Southeast Alaska. In 2015, the bloom season stretched from May to September.

Dinophysis sp

- TOXIC, but non-fatal. Dinophysis species can produce okadaic acid, which can accumulate in shellfish and cause severe gastrointestinal distress, or Diarrhetic Shellfish Poisoning. These
- toxins also cannot be neutralized by cooking or freezing.

 While okadaic acid exposure is not fatal, evidence from Europ suggests that it could promote tumor growth.
- Dinophysis blooms in warm conditions with stable salinity

Heterosigma akashiwo

- NOT TOXIC to humans. Heterosigma can be toxic to fish, however, and has
 caused millions of dollars in damage to farmed fish in Puget Sound over the
 past few years. It has also been documented to kill wild salmon and crustaceans.
 Heterosigma akashiwo's mechanism to fish and crustaceans is unknown. It
 could be producing an unstable neurotoxin, acting in concert with an unknown
 virus, or be producing radical oxides.
- Blooms are most likely when the water is warm and slighly brackish, as after a large summer rainstorm.

More questions? Find out more about harmful algal blooms, shellfish toxins, and available shellfish tests contacting the Sitka Tribe's Environmental Lab. Phone: 907-747-7356. Email: seator@sitkatribe-nsn.gov.

Southeast Alaska Tribal Toxins

The Southeast Alaska Tribal Toxins (SEAIT) partnership a network of Southeast Alaskan Tribes, university searchers, non-profit organizations, and commercial wer fisthermen. Together, the network monitors mmunities across Southeast for harmful algal blooms at toxic shellfish.

ivory year, Alaskans are hospitalized for Paralytic Shellfish sisoning (PSP), a life-threatening illness caused by eating nataminated shellfish. SEATT members are working to duce the risks of PSP and related illnesses from wild ellfish by monitoring local plankton and collecting ellfish samples. As the partnership has grown, SEATT embers have also started to monitor a wider range of ean conditions, map out algal cyst beds, and to improve ar ability to communicate results to the public.

arability to communicate results to the public.

Phytoplankton Monitoring

Unsafe shellfish are generally caused by a large increase of toxic plankton, or harmful algal bloom. To catch these blooms early, SEATT members collect a plankton sample from one or more sites in their communities. SEATT members then analyze the sample under a microscope, looking for potentially harmful species and quantifying their abundance. If target species are present, members then filter a water sample and mail the filters to the Sitka Tribe's lab (STAERL). Phytoplankton monitoring takes place every week of the year at every SEATT sites. All relevant data is uploaded to a database, then shared with the public.

tka Tribe of Alaska Environmental Regulatory Lab In November 2015, the Sitka Tribe of Alaska unpacked the last box equipment for its new lab. This lab allows the SEATT partnership

Fequipment for its new lab. This lab allows the SEATT partnership test both water samples and shellfish for toxins in the event of a rumful algal bloom. The lab is also available to recreational shellfish irvesters. Harvesters can get results on a sample of their collection tihin 24 hours, allowing them to easily keep the rest of their shellfish ive while waiting to ensure that they're safe.

Currently, the lab uses an enzyme-based test to look for saxitoxin domoic acid that is fast, cheap, and effective. In March of 2016, TAERL will also add a new technique for saxitoxin testing called the Receptor Binding Assay. This technique has been approved for summercial samples and will allow STAERL to test Southeast dive roducts by early 2017.

lore questions
