Application of DNA-based tools for algal bloom monitoring

April 27, 2017

Bend Genetics Tim Otten, PhD, MPH Bend Genetics, LLC 87 Scripps Dr Ste 108 Sacramento, CA 95825 ottentim@bendgenetics.com www.bendgenetics.com

Presentation overview

Case studies to illustrate how different molecular tools can be used for monitoring and risk assessment and interpretation of these types of data

- Real-time quantitative PCR (QPCR)
- Amplicon sequencing (DNA barcoding)
- Shotgun metagenomics

Variable risks associated with certain CyanoHAB taxa or from mixed assemblages

 $\overline{}$

Overview of common genetic tools

- Polymerase Chain Reaction (PCR) the amplification of specific DNA sequences using complementary synthetic DNA molecules (primers)
 - Sequence information is required in order to design assays
 - Assays can be designed to be strain-specific or universal
- Amplicon Sequencing PCR products (amplicons) are barcoded (indexed), then deeply sequenced in parallel
 - Used to estimate the <u>relative abundance</u> of targeted organisms in each sample
 - Not a practical method for public health monitoring, but great for research
- Real-Time Quantitative PCR (QPCR) same concept as regular PCR, but includes a fluorescent dye or probe allowing for <u>absolute quantification</u> of gene copies
 - Used in a tiered monitoring framework; high throughput & quick time to results
 - Assumes gene copies/mL equivalent to cells/mL for single copy genes targeted
- Shotgun metagenomics DNA molecules are fragmented and massively sequenced without any amplification step. The generated sequences are assembled into larger fragments of individual genomes.
 - Longer time required for analysis, but useful for assigning specific functions (e.g., toxin or taste-and-odor production) to specific organisms

 Culture-free method

Genetics of Klamath River Microcystis blooms

 \bullet

Sample collection & archival

Collect water sample and concentrate by vacuum filtration

- Filter type is not critical, glass fiber or membrane filters work
- Larger pore sizes (e.g., < 1 µm) will selectively retain cyanobacteria and other algae
- Small pore sizes (e.g., 0.2 μm) retain all bacteria
- Don't freeze water samples before filtering --- cells lyse=DNA lost
- Record volume filtered, required for QPCR quantification
- Store filters in microcentrifuge tubes at -20°C; stable for years
 - Samples can be archived and batch processed

Conclusions

- QPCR is a useful proxy for cyanotoxin risks that is best used in a tiered monitoring framework
 - Assays are selected based on taxa present, samples with elevated toxin or T&O gene concentrations are candidates for toxin testing.
- Because DNA is amplified, toxigenic cells can be detected sooner than other methods
- QPCR can also be used for source tracking or benthic surveys
- Amplicon sequencing can be used to generate relative abundances of microbial taxa and/or phytoplankton when data are not time-sensitive
- Shotgun metagenomics allows for culture-free identification of problematic taxa
 - Data can be used to improve existing QPCR assays or develop novel ones

Thanks for your attention!
