OFFICE OF PREVENTION, PESTICIDES AND TOXIC SUBSTANCES

Date: 23 February 2006 Chemical Code: 044309 DP Barcodes: 326569, 326640, 326590, 326583

### **MEMORANDUM**

- **SUBJECT:** Section 18 Request for Use of Clothianidin on Sugar Beet Seed to Control the Beat Leafhopper (Vector of Beet Curly Top Virus).
- FROM: Jennifer Leyhe, M.S., Biologist James Star 23 7eb ble Ronald Parker, Ph. D., Senior Environmental Engineer Ronald D borker 2/23/66 Environmental Risk Branch 5 Environmental Fate and Effects Division 7507C
- **THROUGH:** Jean Holmes, Acting Branch Chief Jean Holmes, 2, Environmental Risk Branch 5 Environmental Fate and Effects Division 7507C
- TO: Stacie Groce, Risk Manager Reviewer Dan Rosenblatt, Risk Manager Emergency Exemption Section 1 Registration Division

The Environmental Fate and Effects Division (EFED) have completed its review of a Section 18 Emergency Exemption request (DP Barcode 326590) for the treatment of clothianidin to sugar beet seed in treatment facilities in Colorado, North Dakota, Oregon, and Wyoming from 15 January 2006 to 31 July 2006. These seeds would then be planted to control leaf hoppers (vector of beet curly top virus) in Colorado, Idaho, Montana, Oregon, Washington, and Wyoming. The State Departments of Agriculture in Colorado, North Dakota, Oregon, and Wyoming are requesting the commercial application of 60g a.i. per ~100,000 seeds (~1 kg by weight of raw seeds). A maximum of 1 treatment may be made to sugar beet seed prior to shipping. They suggest this would amount to 30 g a.i. clothianidin/Acre (1.6 oz a.i./Acre or 0.07 lb/Acre).

Based on available effects data and treatment concentration, estimated risk quotient (RQ) values exceed the endangered species level of concern for acute risk ( $RQ \ge 0.1$ ) to birds and acute and chronic risk to birds and mammals. Eleven species of birds and mammals are listed

as endangered or threatened in one or all of the states proposed to plant the treated seeds. However, given that clothianidin is a seed treatment, the potential risk to these species is believed to be low.

Clothianidin's major risk concern from sugar beet treatment is to non-target insects that feed on sugar beet plants because it is highly toxic to honeybees on both contact and oral basis. However pollinating insects will not be at risk because sugar beet plants that are grown for sugar are not allowed to flower. No federally listed threatened or endangered insects are listed in the states proposed to plant the treated seeds.

### **ENVIRONMENTAL FATE CHARACTERIZATION**

Clothianidin appears to be a persistent compound under most field conditions. Based on analysis of the laboratory studies alone, the major route of dissipation for clothianidin would appear to be photolysis if exposure to sunlight occurs (e.g., the measured aqueous photolysis half-life was <1 day and aerobic half-lives were 148 to 1155 days). Although photolysis appears to be much more rapid than other avenues of degradation/dissipation of clothianidin in the laboratory studies, the very slow rate of dissipation that was observed in field studies suggests that photolysis probably is not significant under most actual-use conditions. Photolysis may be quite important in surface waters if residues have reached clear bodies of water and are in solution rather than bound to sediment. Clothianidin is stable to hydrolysis at environmental pHs and temperatures. Degradation is also relatively rapid under anaerobic aquatic conditions (overall half-life of 27 days); however, metabolic degradation occurs very slowly in aerobic soil. Clothianidin is mobile to highly mobile in the laboratory [soil organic carbon partition coefficients (Koc) values were 84 to 129 for all test soils except for a sandy loam soil which had a Koc value of 345], although only a modest amount of leaching was observed in the submitted field studies. Previous studies have confirmed that compounds with a similar combination of mobility and persistence characteristics have a potential to leach to ground water at some use sites. Volatilization is not expected to be a significant dissipation process.

### EFFECTS CHARACTERIZATION Terrestrial Animals

According to registrant submitted studies clothianidin is practically non-toxic to moderately to birds and mammals and highly toxic to honeybees. Species toxicity values are listed in **Table 1**. The most sensitive terrestrial species are Japanese quail (*Coturnix coturnix japonica*, LD<sub>50</sub> = 423 mg/L), mouse (*Mus musculus*, LD<sub>50</sub> = 389-465 mg/kg/day), and honeybee (*Apis mellifera*, LD<sub>50</sub> = 0.0037  $\mu$ g ai/bee).

Table 1. Acute effect (mortality) concentrations  $(LD_{50}/LC_{50})$  for terrestrial animals following exposure to clothianidin. Source: EFED Science Chapter

Chronic toxicity data are available for birds, mammals, and beetles (**Table 2**). Northern bobwhite quail showed adverse effects to eggshell thickness. Rats had decreased body weight gains and delayed sexual maturation (males only); decreased absolute thymus weight in F1 pups (both sexes), increased stillbirths (F1 and F2 litters); and decreased sperm mobility and increased number of sperm with detached heads (F1 and F2 litters). Effects to rabbits included premature deliveries, decreased gravid uterine weights, and increased litter incidence of missing lobe of the lung per fetus. Rove beetles had decreased number of progeny in the reproductive study.

# Table 2. Chronic effect concentrations (NOAEC/LOAEC) for terrestrial animals following exposure to clothianidin. Source: EFED Science Chapter

<sup>1</sup> Decreased body weight gains and delayed sexual maturation (males only); decreased absolute thymus weight in F1 pups (both sexes), and increased stillbirths (F1 and F2 litters).

<sup>2</sup> Decreased sperm mobility and increased number of sperm with detached heads (F1 and F2 litters).

<sup>3</sup> Premature deliveries, decreased gravid uterine weights, and increased litter incidence of missing lobe of the lung per fetus.

ppm conversion based on:

1 mg/kg/day = 20 ppm in adult rats, 10 ppm in younger rats, 7 ppm in mice and 33 ppm in rabbits. (Nelson, 1975)

<sup>5</sup> ppm value determined from study.

#### **Aquatic Animals**

**Table 3** lists acute effects concentrations of the most sensitive aquatic species. Benthic invertebrate (*Chironomus riparius*, 48-hr  $EC_{50}$ =0.022 mg/L) and mysid shrimp (*Americamysis bahia*, 96-hr  $LC_{50}$ =0.051 mg/L) are the most sensitive aquatic invertebrates listed while rainbow trout (*Oncorhynchus mykiss*, 96-hr  $LC_{50}$ > 105 mg/Land sheepshead minnow (*Cyprinodon variegatus* 96-hr  $EC_{50}$ > 93.6 mg/L) are the most sensitive fish. Based on these data, clothianidin is classified as practically nontoxic to very highly toxic to aquatic invertebrates and practically non-toxic to slightly toxic to fish on an acute exposure basis.

Table 3. Acute effect concentrations ( $LC_{50}/EC_{50}$ ) for aquatic animals and plants following exposure to clothianidin. Source: EFED Science Chapter

Chronic Toxicity data are available for freshwater fish and invertebrates and estuarine/marine invertebrates (**Table 4**). No chronic data were submitted for estuarine/marine fish. A chronic early life stage study conducted on the fathead minnow showed that exposure has the potential to affect length and dry weight of freshwater fish. Exposure to daphnids resulted in reproductive effects, including the reduced number of juveniles produced per adult. The data submitted for mysid shrimp indicate that clothianidin reduced the number of young per reproductive day.

## Plants

### Terrestrial

The studies that were submitted for terrestrial plants tested formulated products of clothianidin (49.3% TI-435 50% WDG). The results of these studies showed that exposure elicited no effect (that is,  $\geq 25\%$ ) on non-target terrestrial plants.

### Aquatic

Studies submitted for aquatic plants (duckweed and green alga) showed that exposure to clothianidin reduced biomass of aquatic non-vascular plants and increased the incidence of necrotic fronds in aquatic vascular plants (**Table 5**).

# Table 5. Effect concentrations (EC<sub>50</sub>/NOAEC) for aquatic plants following exposure to clothianidin. Source: EFED Science Chapter

### **RISK CHARACTERIZATION**

#### **Risk Estimation**

To evaluate the potential risk to non-target organisms from the proposed use of clothianidin, risk quotients (RQs) are calculated from the ratio of estimated environmental concentrations (EECs) to toxicity values. RQs are then compared to levels of concern (LOCs) used by the Office of Pesticide Programs to indicate potential risk to non-target organisms and the need to consider regulatory action.

### **Terrestrial** Animals

The EFED terrestrial exposure model T-REX (T-REX, Version 1.2.3; **Appendix A**) is used to estimate exposures and risks to avian and mammalian species. The model provides estimates of exposure concentrations and risk quotients (RQs). The acute RQs for birds and mammals are 0.24 and 0.01, respectively. The chronic RQs for birds and mammals are 1.55 and 1.62, respectively. The avian acute RQ exceeds the LOC (0.01) for endangered species. The acute RQ for mammals did not exceed any LOCs. However, both the bird and mammal RQs exceed the chronic risk to non-target organisms.

# Aquatic Animals

To assess risk of clothianidin to non-target aquatic animals (i.e., fish and invertebrates) and plants (i.e., macrophytes and algae), surface water EECs were obtained from the PRZM/EXAMS model (Appendix B). Input parameters are shown in Table 6.

| Parameter                                       | Value                  | Source   | Comments  |
|---|------------------------|--|---|

| Crop name                                       | Sugar beet seed        | Proposed label   |   |
| Maximum application rate (lb/acre)              | seed=0.07              | Proposed label   |   |
| Number of applications                          | seed treatment=1       | Proposed label   |   |
| Method of application                           | seed treatment         | Proposed label   |   |
| Incorporation depth<br>(inches)                 | seed=0.75              | Emergency Request<br>from states   |   |

**Table 7** lists acute risk quotients for the most sensitive species of aquatic vertebrates and invertebrates. All RQs are equal to zero because the concentration in the environment is estimated to be very low. Therefore, no RQ exceeds any LOCs.

| Species   | Toxicity (mg/L)           | EEC(mg/L)       | RQ  |

### Table 7. Acute and chronic RQs for aquatic animals and plants.

### **Risk Discussion**

Under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA), all pesticides sold or distributed in the United States must be registered with EPA. Clothianidin is currently registered with the U.S. EPA for use as an insecticide for seed treatment use on corn, rapeseed, and canola. Sugar beet seed treatment is not currently registered.

Clothianidin's major risk concern from sugar beet treatment is to non-target insects because of its systemic nature. Acute toxicity studies to honey bees show that clothianidin is highly toxic on both contact and oral basis. Any non-target insects that feed on sugar beet plants would be at risk; however, insects that are pollinators would not be at risk because sugar beet plants that are grown for sugar are not allowed to flower.

Based on proposed use, acute risks to small birds and mammals are unlikely, except for endangered birds should exposure actually occur. If these organisms are exposed to clothianidin on a chronic basis there may be risk to both birds and mammals; however, considering the mode of agricultural practice of incorporating seeds during planting, EFED believes that clothianidin seed treatment should result in minimal risk.

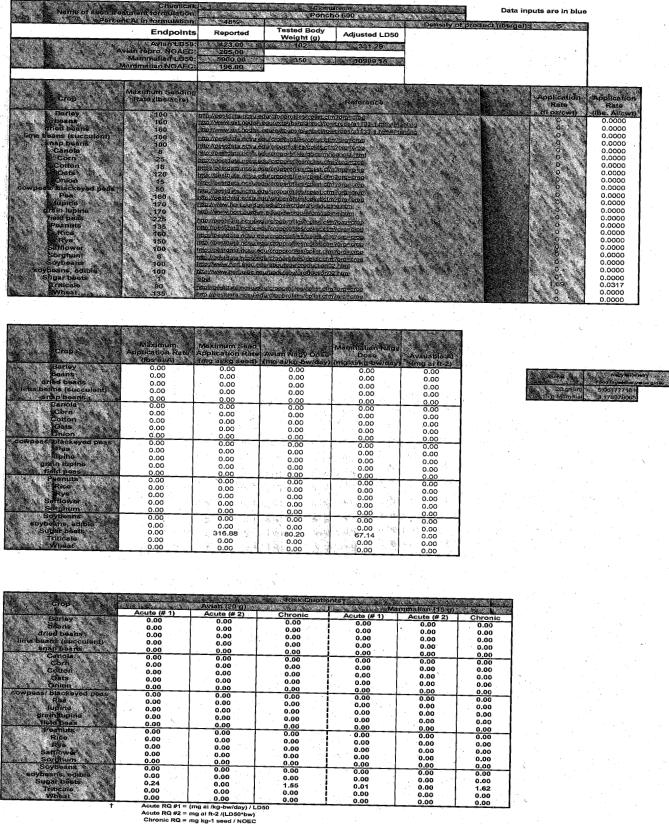

A Tier II assessment for aquatic species (using the PRZM/EXAMS model) indicates that no level of concern was exceeded for aquatic animals. Clothianidin is not expected to move to the aquatic environment from the seeds; therefore risk is low to aquatic organisms.

Clothianidin does not appear to present risk to terrestrial plants (there were no significant effects in the studies submitted). In addition, it does not appear to present risk to aquatic vascular or nonvascular plants.

### **Endangered** Species

At the proposed treatment rate evaluated for clothianidin, acute risk to endangered species LOCs are exceeded for birds and chronic LOCs are exceeded for both birds and mammals. EFED does not calculate RQs for insects; however, based on toxicity values, risk to non-target insects that feed on sugar beet plants may be high. Pollinating insects, on the other hand, will not be at a great risk because sugar beet plants grown for sugar are not allowed to flower. Based on the LOCATES software (Version 2.9.11) output (Appendix C), 11 species of birds and mammals are listed as endangered or threatened in one or all of the states proposed to plant the seeds. However, no Federally listed threatened or endangered insects are listed in those same states. Given that clothianidin is a seed treatment, the potential risk to these species is believed to be low.
