MEMORANDUM

SUBJECT: Malathion: Updated Revised Occupational Exposure and Risk Assessment for the Interim Reregistration Eligibility Decision (IRED) Document. (DP Barcode: D286796; Chemical Number: 057701; EPA MRID Nos.: 45005910, 45491901, 45138202, 45491902, 45138201, 45469501)

FROM: Jack Arthur, Environmental Scientist
Registration Action Branch 3
Health Effects Division (7509C)

THRU: Steve Dapson, Branch Senior Scientist
Registration Action Branch 3
Health Effects Division (7509C)

TO: Paula A. Deschamp, Biologist
Reregistration Branch 2
Health Effects Division (7509C)

The occupational exposure and risk assessment for the HED IRED Chapter for Malathion is attached. The previous version of this assessment appeared in the HED Revised Occupational and Residential Exposure and Risk Assessment for the Reregistration Eligibility Decision (RED) document, dated September 14, 2000. In a meeting on May 20, 2002, the HED's Hazard Identification Assessment Review Committee (HIARC) recommended new toxicity endpoints and uncertainty factors for Malathion. This current document has been updated to reflect those HIARC changes. An exposure assessment for malathion residential uses has been prepared as a separate document (ref.: D283741). Substantial assistance was rendered on this document by Seyed Tadayon (HED).

TABLE OF CONTENTS

1.0 Executive Summary

In this document, which is for use in EPA's development of the Malathion Interim Reregistration Eligibility Decision (IRED) Document, HED presents its review of the potential human health risks from occupational exposure to malathion. Occupational exposure may result from malathion agricultural uses (i.e., multiple food-use crops) and non-agricultural uses (i.e., outdoor residential vegetable gardens, home orchards, ornamentals and perimeter house treatments, and wide-area mosquito treatment). Exposure may occur to both handlers and postapplication workers who enter and conduct activities in treated use sites. A non-occupational risk assessment for residential malathion use sites is presented in a separate HED document[5]. Risks to residential handlers did not exceed HED's level of concern for short- and intermediate-term exposures. Because occupational exposures are not expected exceed those of residential handlers, (i.e., occupational risks from residential applications are not expected to exceed HED's level of concern) they are not assessed in this document.

The HIARC selected cholinesterase inhibition as the toxicity endpoint for dermal exposure (Target MOE = 100), and histopathologic lesions as the toxicity endpoint for inhalation exposure (Target MOE = 1000). Even though dermal and inhalation exposures have separate endpoints, it is believed that the contribution of inhalation exposure to the cholinesterase endpoint should be accounted for. Therefore, in calculating the risks for cholinesterase inhibition, dermal and inhalation exposure estimates were combined, and the resulting Total MOEs compared to the Target MOE of 100. The following is a brief overview of the results of this occupational risk assessment:

Occupational Handlers

Most **mixer/loader scenarios** do not reach the target MOE of 100 at baseline clothing (i.e., long pants, long sleeved shirt, shoes & socks). With the addition of gloves, most mixer/loader scenarios reach the target MOE, except for those that involve high application rates, large area of treatment, or wettable powder formulations. For these latter exceptions (approximately 17 scenarios), most require additional clothing, a respirator, or engineering controls such as a closed mixing/loading system, in order to reach the target MOE.

All **applicator scenarios** (*except airblast application of EC to apricots, cherries, nectarines, peaches, avocados, figs, chestnuts, pecans, walnuts, citrus fruits and ornamentals, and applying sprays for mosquitoes with a non-thermal fogger)*, reach the target MOE with handlers wearing baseline clothing, and are not of concern to HED. Of the scenarios for which more than baseline protection is necessary, several require engineering controls (i.e., enclosed cab tractors).

All **flagger scenarios** for all formulations and crops reach the target Total MOE of 100 with handlers wearing baseline clothing, and are not of concern to HED.

Occupational Postapplication Workers

All crops and application rates were assessed for postapplication activities ranging from very low to very high contact. Resulting "days after treatment" at which the target MOE of 100 was reached varied from 0 to 6 days. Most activities reach the target MOE on day 0. An REI of 12 hours is established for malathion under the Worker Protection Standard (WPS).

1.1 Purpose

This document is for use in EPA's development of the Malathion Interim Reregistration Eligibility Decision (IRED) Document. In this document, HED presents its assessment of the potential human health risks from occupational exposure to malathion. This document includes only those product formulations and agricultural use sites supported by the basic producer (Cheminova) and IR-4 (listed in a 2/17/98 Agency Memorandum)[1] and reflected by a subsequent communications deleting the residential uses of malathion for broadcast turf treatment and residential dust formulations (Cheminova letters dated March 10, and March 18, 2002)[2,3].

1.2 Criteria for Conducting Exposure Assessments

An occupational exposure assessment is required for an active ingredient if (1) certain toxicological criteria are triggered and (2) there is potential exposure to handlers (mixers, loaders, applicators, etc.) during use or to persons entering treated sites after application is complete. For malathion, both criteria are met.

1.3 Summary of Toxicity Concerns Relating to Occupational Exposures

1.3.1 Acute Toxicity Categories

The toxicological data base for malathion [S-1,2-bis (ethoxycarbonyl)ethyl O,O-dimethyl phosphorodithioate] is adequate and will support reregistration. Table 1 summarizes the acute toxicity values and categories for technical (97%) malathion.

Table 1: Acute Toxicity Categories for Technical Malathion

Test	Results	Toxicity Category
Acute Oral - Rat	LD_{50} = 5400 mg/kg/day ♂ 5700 mg/kg/day ♀	IV
Acute Dermal - Rat	LD_{50} = >2000 mg/kg/day ♀♂	III
Acute Inhalation - Rat	LC_{50} = >5.2 mg/L ♀♂	IV
Primary Eye Irritation - Rabbit	Slight conjunctival irritation; cleared by 7 days	III
Primary Dermal Skin Irritation - Rabbit	Slight dermal irritation (PIS = 1.1)	IV
Dermal Sensitization - Guinea Pig	Not dermally sensitizing	–

1.3.2 Other Endpoints of Concern

The HIARC report (Malathion. Report of the Hazard Identification Review Committee. Makris and Dementi, June 13, 2002; TXR0050804), indicates that there are toxicological endpoints of concern for malathion. See Table 2.

Table 2. Summary of Toxicology Endpoint Selection for Malathion (PC Code 057701)

Exposure Scenario	Dose (mg/kg/day) UF /MOE	Hazard and Exposure Based Special FQPA Safety Factor	Endpoint for Risk Assessment	Study
Dietary Risk Assessments				
Acute Dietary general population including infants and children	LOAEL = 5 mg/kg/day UP = 300[1] Acute RFD = 0.02 mg/kg/day	FQPA SF 3X aPAD. = acute RFD/FQPA SF = 0.007 mg/kg/day	LOAEL = 5 mg/kg/day based on RBC ChE. in offspring	Comparative cholinesterase single dose oral study in the rat
Chronic Dietary all populations	NOAEL = 2.4 (Regulatory dose = 2.0 mg/kg/day) UP = 100 Chronic RFD = 0.02 mg/kg/day	FQPA SF 3X cPAD = chronic RFD/FQPA SF = 0.007 mg/kg/day	LOAEL = 26 mg/kg/day based on plasma chE.	Chronic/carcinogenicity oral study in the rat
Non-Dietary Risk Assessments				
Incidental Oral Short- and Intermediate- Term (1 - 30 Days and 1 - 6 Months) Residential Only	LOAEL = 5 mg/kg/day MOE = 1000 [1]	10X	LOAEL = 5 mg/kg/day based on RBC Che. in offspring	Comparative cholinesterase single and multiple dose oral study in the rat

Exposure Scenario	Dose (mg/kg/day) UF /MOE	Hazard and Exposure Based Special FQPA Safety Factor	Endpoint for Risk Assessment	Study
Dermal (Short- and Intermediate-Term)				
Residential (children)[2]	Oral LOAEL = 5 mg/kg/day MOE = 1000 [1]	10X	LOAEL = 5 mg/kg/day based on RBC Che. in offspring	Comparative cholinesterase single and multiple dose oral study in the rat
Residential (adults)	Dermal NOAEL = 50 mg/kg/day MOE = 100	1X	LOAEL = 300 mg/kg/day based on plasma and RBC Che. (♂, ♀) and brain Che. (♀)	21-day dermal study in rabbits
Occupational (adults)	Dermal NOAEL = 50 mg/kg/day MOE = 100	N/A	LOAEL = 300 mg/kg/day based on plasma and RBC Che. (♂, ♀) and brain Che. (♀)	21-day dermal study in rabbits
Dermal (Long-Term) [2]				
Residential (children)	Oral NOAEL = 2.4 mg/kg/day (Regulatory dose = 2.0 mg/kg/day) MOE = 300	3X	NOAEL = 26 mg/kg/day based on plasma Che.	Chronic/carcinogenicity oral study in the rat
Occupational and Residential (adults)	Oral NOAEL = 2.4 mg/kg/day (Regulatory dose = 2.0 mg/kg/day) MOE = 100	1X	NOAEL = 26 mg/kg/day based on plasma Che.	Chronic/carcinogenicity oral study in the rat
Inhalation (All Durations) [3]				
Occupational and Residential (all populations)	Inhalation LOAEL= 0.1 mg/L (25.8 mg/kg/day) MOE =1000 [4]	1X	LOAEL= 0.1 mg/L (25.8 mg/kg/day) based on histopathology in respiratory epithelium	90-day inhalation study in rats
Residential (children) [5]	Inhalation NOAEL= 0.1 mg/L (25.8 mg/kg/day) MOE = 300 (chE.)	3X	LOAEL = 0.45 mg/L (115.1 mg/kg/day) based on plasma and RBC Che.	90-day inhalation study in rats
Occupational and Residential (adults) [5]	Inhalation NOAEL= 0.1 mg/L (25.8 mg/kg/day) MOE = 100 (chE.)	1X	LOAEL = 0.45 mg/L (115.1 mg/kg/day) based on plasma and RBC Che.	90-day inhalation study in rats
Cancer	Classification: Suggestive evidence of carcinogenicity			

[1] UP = 1000 [10x for interspecies extrapolation and 10x for intraspecies variations and 10x for Total FQPA Safety Factor; 3x uncertainty factor for a LOAEL to NOAEL ($_{UFA}$) and 3x for Hazard-Based Special uncertainty factor.]

[2] Since an oral LOAEL/NOAEL was selected, a dermal absorption factor of 10% should be used in route-to-route extrapolation.

[3] Absorption via the inhalation route is assumed to be equivalent to oral absorption.

[4] MOE = 1000 [10x for interspecies extrapolation and 10x for intraspecies variations and 10x for a LOAEL to NOAEL ($_{UFA}$) and for the severity of the effect.]

[5] Use for aggregate assessment only.

1.4 Incidents Reports (see J. Blondell and M. Spann, 08/18/98, D247492)

1.5 Summary of Use Patterns and Formulations

1.5.1 Occupational-Use Products

Products containing the insecticide, malathion, are intended for both occupational and residential uses. Malathion occupational-use products assessed by HED include those for agricultural uses (i.e., multiple food-use crops) and non-agricultural uses (i.e., outdoor residential vegetable gardens, home orchards, ornamentals and perimeter house treatments, and wide-area mosquito treatment). Exposure may occur to both handlers and postapplication workers who enter and conduct activities in treated use sites. A non-occupational risk assessment for residential malathion use sites is presented in a separate HED document[5]. In that assessment, risks to residential handlers did not exceed HED's level of concern for short- and intermediate-term exposures. Because occupational exposures are not expected to exceed those of residential handlers, occupational risks from treating residential sites also are not expected to exceed HED's level of concern, and therefore, are not assessed in this document.

1.5.2 Formulation types and percent active ingredient

Based on a July 2002 review of OPP Reference Files System (REFS), there are active registrations for 213 products containing malathion. Malathion, [S-1,2-bis (ethoxycarbonyl)ethyl O,O-dimethyl phosphorodithioate] is an organophosphate insecticide, formulated as a technical (91-95% ai), a dust (1-10% ai), an emulsifiable concentrate (3-82% ai), a ready-to-use (1.5-95% ai), a pressurized liquid (0.5-3% ai), and a wettable powder (6-50% ai). Several of the 95% liquids are intended for Ultra-Low-Volume (ULV) applications.

1.5.3 Registered Occupational Use sites

At this time, malathion is registered for occupational use on terrestrial food and feed crops, indoor food crops, aquatic food crops, terrestrial non-food crops, forestry, indoor non-food, and indoor and outdoor residential. However, the Agency has been informed by the producer (Cheminova) and IR4 that the following occupational use sites will not be supported for reregistration:

All pet uses for all formulations;
All livestock uses with all formulations;
All indoor uses (except stored commodities and storage facilities);
All greenhouse uses (except that mushroom use is presumed to be in mushroom houses for purposes of this assessment);
All open-forest uses;
All seed treatments with all formulations;
All formulations for the following uses:
- Almonds (including hulls and shells)

- Cranberries
- Filberts
- Peanuts (including forage, hay, storage and storage facilities)
- Peavines (including hay)
- Safflower seed
- Soybeans (including hay and forage)
- Sugar beets
- Sunflower seed
- Treated raisin trays

All pressurized can formulations.
All broadcast turf uses
Dust formulations for residential use sites

Consequently, most of these use sites, while they may be included in the list of currently registered uses, have not been specifically included in the occupational exposure/risk assessment in this IRED document. This assessment excludes the above uses, based on the presumption that their reregistration will be prohibited in the mitigation phase of the reregistration process.

The specific occupational use sites in this IRED are summarized below (Table 3).

Table 3. Summary of Occupational Use Sites

Crop Group	Formulation	Use Site	Rate (lb ai/acre, unless otherwise stated)	Application Equipment
Non-grass animal feed	EC	alfalfa, clover, lespedeza, lupin, vetch	1.25	Groundboom, Aerial, Chemigation
	ULV	alfalfa, clover, lespedeza, lupin, vetch	0.61	
Pome fruits	EC	apples, pear, quince	1.25	Airblast, Aerial
Stone fruits	EC	apricots, cherries (sweet and tart),nectarine, peach	3.75	Airblast, Aerial
	ULV	cherries (sweet and tart)	1.22	
Stalk and stem vegetables	EC	asparagus	1.25	Groundboom, Aerial
Tropical and subtropical fruits	EC	avocado,	4.7	Groundboom, Airblast, Aerial
		figs	2.5	
		guava, mango, papaya, passionfruit	1.25	
		pineapples	5	
Cereal grains	EC	barley, corn, oats, rice, rye, sorghum, wheat, wild rice	1.25	Groundboom, Aerial, Chemigation
	ULV	barley, corn, oats, rice, rye, sorghum, wheat, wild rice	0.61	

Root and tuber vegetables	EC	garden beets, carrot, horseradish, parsnip, radish, rutabaga, salsify, turnip	1.25	Groundboom, Aerial
		potatoes, sweet potatoes,chayote root and yams	1.56	
Berries	WP	blackberry, boysenberry, dewberry, loganberry, raspberry	2	Groundboom, Aerial
		blueberries	1.25	
	ULV	blueberries	0.76	
Brassica leafy vegetables	EC	broccoli, broccoli raab, brussels sprouts, cabbage, cauliflower, collard, kale, kohlrabi, mustard green	1.25	Groundboom, Aerial
Cucurbit vegetables	EC	cantaloupe, melon, pumpkin, winter squash, watermelon	1	Groundboom, Aerial
		cucumber and summer squash, Chayote fruit	1.88	
Leafy vegetables	EC	celery	1.25	Groundboom, Aerial
		dandelion, parsley, spinach, Swiss chard,	2	
		endive and lettuce	1.88	
		watercress	1.25	
Tree nuts	EC	chestnuts	5	Airblast, Aerial
		macadamia nuts	0.94	
		pecans, walnuts	2.5	
Oilseed	EC	cotton	2.5	Groundboom, Aerial
	ULV	cotton	1.22	
	EC	flax	0.5	
Fruiting vegetables	EC	eggplant, tomato	3.43	Groundboom
		okra	1.5	
Bulb vegetables	EC	garlic, leeks, onion, shallots,	1.56	Groundboom
Citrus fruits	EC	grapefruits, kumquat, lemon, lime, orange, tangelo, tangerines	6.25	Airblast, Aerial
	ULV	grapefruits, lemon, lime, orange, tangelo, tangerines	0.175	
	ULV	kumquat	0.92	
Small fruits	EC	grape	1.88	Airblast
	EC, WP	strawberry	2	Groundboom, Chemigation

Forage grass	EC	grass	1.25	Aerial
	ULV	hay grass	0.92	
Herbs and spices	EC	mint	0.94	Groundboom, Chemigation (Airblast for hops)
		hops	0.63	
		pepper	1.56	
Edible fungi	EC	mushroom	1.7	Low-Pressure Handgun
Legume vegetable	EC	peas	2.5	Groundboom, Aerial, Chemigation
Ornamentals	EC	flowers, shrubs, flowering plants, nursery stock, and woody plants	2.5	Groundboom, Low-Pressure Handwand, Backpack Sprayer
Pine Trees	EC	pine seed orchards, Christmas tree plantations, slash pine plantations, shrubs, shade trees, and forest trees	2.5	Aerial, Chemigation
Grape Root	EC	grape roots	1.9 lb ai per 100 gallons.	Hand or Basket Dipping
Storage Grain Facility	EC	stored commodities such as corn, wheat, barley, oats, and rye	5 lb ai per 20 gallons.	Low-Pressure Handwand, Backpack Sprayer
	Dust		0.3 lbs ai per 1,000 square feet	Power Duster
Agricultural Premises	EC	outside barns, applied as a bait only	0.27 lbai per gal	Low-Pressure Handwand, Backpack Sprayer
Dates	Dust	dates	4.25	Power Duster
Mosquitoes	ULV	mosquitoes	0.23	Aerial
	EC		9.9 lb ai per gal	Non-thermal Truck Fogger
			0.51 lb ai per gal	Thermal Truck Fogger
	EC		0.1 lb ai per gal	Paint brush

2.0 Occupational Exposures and Risks

EPA has determined that there are potential occupational exposures to handlers (i.e., mixers, loaders, applicators), as well as to postapplication workers from the use of malathion. In subsequent sections of this document, occupational exposure and risks are presented in summary tables in two groupings according to formulation; with emulsifiable concentrate (EC), wettable powder (WP) and ready-to-use (RTU) formulations in one group, and ultra-low volume (ULV) formulation in another. Application rates, and consequent risks for ULV formulations are sufficiently lower than EC, WP and RTU formulations, to be presented separately.

2.1 Occupational Handler Exposures and Risks

The anticipated use patterns indicate a number of exposure scenarios, based on the types of equipment and activities used to make malathion applications. These scenarios include:

mixing/loading liquids for groundboom application;
mixing/loading liquids for aerial and chemigation application;
mixing/loading liquids for airblast sprayer;
mixing/loading liquids for dipping;
mixing/loading liquids for a fogger;
loading dusts for power duster;
mixing/loading wettable powders for groundboom application;
mixing/loading wettable powders for aerial and chemigation application;
applying sprays with an airblast sprayer;
applying sprays with a groundboom sprayer;
applying sprays with a fixed-wing aircraft (also covers use of helicopter application);
applying sprays with a truck-mounted fogger;
applying dusts with a power duster;
dipping plants;
mixing/loading/applying liquid with a low pressure handwand;
mixing/ loading/applying with a backpack sprayer;
mixing/ loading/applying with a low-pressure handgun;
mixing/loading/applying with a paintbrush; and
flagging for aerial spray application.

2.1.1 Occupational Handler Exposure Scenarios -- Data and Assumptions

No chemical-specific handler exposure data were submitted in support of the reregistration of malathion. Therefore, an exposure assessment for each scenario was developed, where appropriate data are available, using the Pesticide Handlers Exposure Database (PHED) Version 1.1.[4] PHED was designed by a task force consisting of representatives from the U.S. EPA, Health Canada, the California Department of Pesticide Regulation, and member companies of the American Crop Protection Association. PHED is a generic database containing measured exposure data for workers involved in the handling or application of pesticides in the field (i.e., currently contains data for over 2,000 monitored exposure events). The basic assumption underlying the system is that exposure to pesticide handlers can be calculated using the monitored data as exposure is primarily a function of the physical parameters of the handling and application process (e.g., packaging type, application method, and clothing scenario). PHED also contains algorithms that allow the user to complete surrogate task-based exposure assessments beginning with one of the four main data files contained in the system (i.e., mixer/loader, applicator, flagger, and mixer/loader/applicator).

Users can select data from each major PHED file and construct exposure scenarios that are representative of the use of the chemical. However, to add consistency to the risk assessment process, the EPA in conjunction with the PHED task force has evaluated all data within the system and developed surrogate exposure tables that contain a series of standard unit exposure values for various exposure scenarios. These standard unit exposure values are based on the "best fit" values calculated by PHED. PHED calculates "best fit" exposure values by assessing the distributions of exposures for each body part included in datasets selected for the assessment (e.g., chest or forearm) and then calculating a composite exposure value representing the entire body. PHED categorizes distributions as normal, lognormal, or in any "other" category. Generally, most data contained in PHED are lognormally distributed or fall into the PHED "other" distribution category. If the distribution is lognormal, the geometric mean for the distribution is used in the "best fit" exposure value. If the data are an "other" distribution, the median value of the dataset is used in the calculation of the "best fit" exposure value. As a result, the surrogate unit exposure values that serve as the basis for this assessment generally range from the geometric mean to the median of the selected dataset.[4]

The following assumptions and factors were used to complete this exposure assessment:

- Average body weight of an adult handler is 70 kg. This body weight is used in both the short- and intermediate-term assessment, since the endpoint of concern is not sex-specific (i.e., the cholinesterase inhibition could be assumed to occur in males or females).

- Average work day interval represents an 8 hour workday (e.g., the acres treated or volume of spray solution prepared in a typical day).

- For fogging mosquitoes with a truck-mounted fogger, no PHED data were available; thus, as a surrogate, the PHED baseline unit exposure data for an airblast sprayer (0.36 mg/lb ai for dermal and 4.5 µg/lb for inhalation) were used to calculate dermal and inhalation exposure. In addition, the gallons handled were taken from information provided on the label (EPA Reg. 4787-8) which indicated that a thermal fogger sprays at a rate of 40 gal/hr and a non-thermal fogger sprays at a rate of 4 gal/hr. EPA assumed the fogger was used 4 hrs per day.

- For loading dusts for a power duster, no PHED data were available; thus, as a surrogate, the PHED baseline unit exposure data for wettable powders (3.7 mg/lb ai for dermal and 43 µg/lb for inhalation) were used to calculate dermal and inhalation exposure. Applicator exposure from using power dusters is a data gap.

- It is assumed that mushroom houses are treated with malathion to control flies as often as twice per week during an approximately 9-month period when pest pressure is at its greatest (April - December). The average area treated per day is assumed to be 16,000 ft^2. (Personal communication with Dr. Clifford Keil,

Associate Professor, Univ. of Delaware, Oct. 16, 2002). Unit exposure values for a low-pressure handgun (mixer/loader/applicator, liquid flowable) from a study conducted by the Outdoor Residential Exposure Taskforce (ORETF) were used as the closest surrogate for the application equipment employed in mushroom houses.

- For agricultural uses, exposure calculations were based on the maximum application rates used in residue field trial studies in support of food tolerances and supported by the primary producer, Cheminova. For non-agricultural uses, maximum application rates were identified, as listed on the available malathion labels and LUIS reports.

- When scenario-specific data are not available, HED calculates unit exposure values using generic protection factors that are applied to represent the use of personal protective equipment (PPE) and engineering controls.

2.1.2 Occupational Handler Exposure and Risk Estimates

Both short- and intermediate-term exposures are expected to occur to handlers from registered malathion use patterns. Chronic exposure is not expected for handlers, and therefore is not assessed. Handler's calculated daily dermal and inhalation exposures to malathion were used to calculate the daily doses, and consequent risks to those handlers. Potential daily dermal exposure was calculated using the following formula:

$$\textit{Daily Dermal Exposure}\left(\frac{mg\ ai}{day}\right) = \textit{Unit Exposure}\left(\frac{mg\ ai}{lb\ ai}\right) \times \textit{Use Rate}\left(\frac{lb\ ai}{A}\right) \times \textit{Daily Acres Treated}\left(\frac{A}{day}\right)$$

A dermal absorption value was not needed for short-/intermediate-term adult dermal exposure because the dermal NOAEL was based on a 21-day dermal study.

Potential daily inhalation exposure was calculated using the following formula:

$$\textit{Daily Inhalation Exposure}\left(\frac{mg\ ai}{day}\right) =$$
$$\textit{Unit Exposure}\left(\frac{\mu g\ ai}{lb\ ai}\right) \times \textit{Conversion Factor}\left(\frac{1mg}{1{,}000\ \mu g}\right) \times \textit{Use Rate}\left(\frac{lb\ ai}{A}\right) \times \textit{Daily Acres Treated}\left(\frac{A}{day}\right)$$

Inhalation absorption is assumed to be equivalent to oral absorption (i.e., 100%).

The handler's daily dermal and inhalation dose was calculated using a 70 kg body weight for all toxicity endpoints as follows:

$$\text{Daily Inhalation Dose}\left(\frac{\text{mg ai}}{\text{kg/day}}\right) = \text{Daily Inhalation Exposure}\left(\frac{\text{mg ai}}{\text{day}}\right) x \left(\frac{1}{\text{Body Weight (kg)}}\right)$$

$$\text{Daily Dermal Dose}\left(\frac{\text{mg ai}}{\text{Kg/Day}}\right) = \text{Daily Dermal Exposure}\left(\frac{\text{mg ai}}{\text{Day}}\right) x \left(\frac{1}{\text{Body Weight (Kg)}}\right)$$

The calculations of both the daily dermal dose and the daily inhalation dose of malathion received by handlers were used to calculate the short-/intermediate-term dermal and inhalation margins of exposure (MOEs), or risk. The dermal MOE was calculated using a NOAEL of 50 mg/kg/day, and the inhalation MOE was calculated using a NOAEL of 25.8 mg/kg/day. The following formula describes the calculation of a dermal MOE:

$$\text{Dermal MOE} = \frac{\text{NOAEL (mg/kg/day)}}{\text{Dermal Daily Dose (mg/kg/day)}}$$

The following formula describes the calculation of an inhalation MOE:

$$\text{Inhalation MOE} = \frac{\text{NOAEL (mg/kg/day)}}{\text{Inhalation Daily Dose (mg/kg/day)}}$$

The HIARC selected cholinesterase inhibition as the toxicity endpoint for dermal exposure (Target MOE = 100), and histopathologic lesions as the toxicity endpoint for inhalation exposure (Target MOE = 1000). Even though dermal and inhalation exposures have separate endpoints, it is believed that the contribution of inhalation exposure to the cholinesterase endpoint should be accounted for. Therefore, in calculating the short- and intermediate-term risks for cholinesterase inhibition, dermal and inhalation exposure estimates were combined, and the resulting Total MOEs compared to the Target MOE of 100. However, the NOAELs are different for dermal (50 mg/kg/day) and inhalation (25.8 mg/kg/day). In order to calculate a Total MOE, the reciprocals of the dermal and inhalation MOEs are combined and divided into 1. The above operations are represented as follows:

MOE_{dermal} = calculated dermal MOE

$MOE_{inhalation}$ = calculated inhalation MOE

$$\text{Total MOE} = \frac{1}{\frac{1}{MOE_{dermal}} + \frac{1}{MOE_{inhalation}}}$$

A total MOE ≥ 100 does not present a concern for handler exposure (based on the cholinesterase inhibition endpoint). An MOE ≥ 1000 for inhalation alone, does not present a concern for handler exposure (based on the histopathologic lesion endpoint).

Total MOEs (developed using PHED Version 1.1 surrogate data) for occupational handlers wearing baseline protective clothing, and for various other combinations of PPE are summarized in Tables 4 - 9. Tables 4 and 5 cover application rates and formulations used on agricultural crops. For Tables 4 and 5, estimated MOEs in shaded areas do not reach the Target MOEs at the level of PPE indicated. Attachment 1 of this document provides more detailed information on exposure doses and risks. Tables 6 - 9 cover application rates and formulations for nonfood use sites (plus malathion use on dates, grape roots and stored grain). For Tables 6 - 9, estimated MOEs in shaded areas reach or exceed the Target MOEs at the level of PPE indicated, and are not of concern to HED.

Table 4. Summary of Short- and Intermediate-Term Handler Risk for Malathion at Various Levels of PPE (EC, WP and RTU Application Rates)

Exposure Scenario (Scenario #)	Crop groups (crops)	Application Rate lb ai / acre	Daily Area Treated Acres/ day	Total MOE Baseline	Total MOE PPE1	Total MOE PPE2	Total MOE PPE3	Total MOE PPE4	Total MOE PPE5	Total MOE PPE6	Total MOE Eng. Control
Mixer/Loader											
Mixing/Loading Liquids for Groundboom application (1)	Non-grass animal feed(alfalfa)	1.25	200	4.8	550	600	600	720	800	810	1600

Footnotes:

a Baseline dermal unit exposure represents long pants, long sleeved shirt, no gloves, and open mixing/loading. PHED Surrogate Exposure Guide - Draft. August 1998.

b Baseline inhalation unit exposure represents no respirator. PHED Surrogate Exposure Guide - Draft. August 1998.

c Crop types or targets are selected as follows:
- 1 Based on labeled maximum rates for ornamentals and pine trees (EPA Reg. 655-777 and 67760-1).
- 2 Based on labeled maximum rates for mosquitoes including standing water (based on residue field trials) and terrestrial uses (EPA Reg. 34704-108).
- 3 Based on labeled maximum rates for mosquitoes applications for ULV-type (EPA Reg. 4787-8).
- 4 Based on maximum application rates for grape root dip.
- 5 Based on maximum application rates for stored grain (surface treatments to corn, wheat, barley, oats, rye with dust formulations and treatment of grain storage facilities with EC formulations.
- 6 Based on maximum application rates for poultry premises and agricultural premises used as a bait spray.
- 7 Based on maximum application rates from residue field trials in support of food tolerances for mushrooms.

d Amount handled per day are from EPA estimates of acres treated, gallons applied, or square feet treated.

e Daily Dermal Exposure (mg/day) = Dermal Unit Exposure (mg/lb ai) x Application Rates (lb ai/acre; lb/gal; and ai/sq ft) x Amount Handled per day (acres, gallons, sq. ft.).

f Daily Inhalation Exposure (mg/day) = Inhalation Unit Exposure (μg/lb ai) x (1 mg/1,000 μg) Conversion x Application rate (lb ai/acre; lb/gal; and ai/sq ft) x Amount Handled per day (acres, gallons, sq. ft.)

g PHED data for mixing/loading wettable powders is used as a "surrogate" for mixing/loading dusts.

h PHED data for applying sprays with an airblast sprayer is used as a "surrogate" for applying with a fogger.

i Because the dermal unit exposure in PHED includes protection from use of gloves, dermal risk is assessed in Table 8, and not under "Baseline" scenarios in Table 7.

NF Not Feasible.

NF Not Feasible
NA Not Applicable - Because previous level of mitigation resulted in total MOE ≥100.
None There are no unit exposure values for engineering controls for the equiprment used or the formulation type (i.e., water-soluble bags are only used with wettable powders)

2.1.3 Summary of Risk for Occupational Handlers and Confidence in Exposure and Risk Estimates

Total MOEs of equal to, or greater than 100 (for the cholinesterase inhibition endpoint), **do not exceed HED's level of concern. MOEs for inhalation alone, of equal to, or greater than 1000** (for the histopathological lesions endpoint), **do not exceed HED's level of concern.**

Short- and Intermediate-term Occupational Handler Risks

The calculations of short-/intermediate-term risks to occupational handlers for mixing, loading and applying malathion for occupational use sites, formulations and application rates are summarized above in Tables 4 - 9. Commercial applications of malathion at residential use sites (i.e., home gardens, ornamentals and orchards, and perimeter house treatments) were not assessed in this document. When these activities were assessed for homeowners[5], all risks reached or exceeded the target MOE for the short- and intermediate-term exposure endpoint, and, therefore they also will reach or exceed the target MOE for the same activities performed by professionals. Highlights of the handler assessment include the following:

Mixers/Loaders:

Most mixer/loader scenarios do not reach the target MOE of 100 at baseline clothing (i.e., long pants, long sleeved shirt, shoes & socks). With the addition of gloves, most mixer/loader scenarios reach the target MOE, except for those that involve high application rates, large area of treatment, or wettable powder formulations. For these latter exceptions, most require addtitional clothing, a respirator, or engineering controls such as a closed mixing/loading system, in order to reach the target MOE.

Applicators:

All applicator scenarios (*except airblast application of EC to apricots, cherries, nectarines, peaches, avocados, figs, chestnuts, pecans, walnuts, citrus fruits and ornamentals, and applying sprays for mosquitoes with a non-thermal fogger)*, reach the target MOE with handlers wearing baseline clothing, and are not of concern to HED. Of the scenarios for which more than baseline protection is necessary, several require engineering controls (i.e., enclosed cab tractors). Note: Reliable unit exposure data for aerial application only exist in PHED for closed cockpit fixed-wing aircraft (i.e., engineering controls), and therefore, only this mitigation option has been assessed.

Flaggers:

All flaggers for all formulations and crops reach the target Total MOE of 100 with handlers wearing baseline clothing, and are not of concern to HED.

Application to Dates

Data for assessing the risk from loading/applying malathion dusts with a power duster to treat date crops are not available in PHED. As seen in the tables above, using unit exposure values from PHED for mixers/loaders of wettable powders as a reasonable surrogate for loading dusts, the risk for handlers at baseline does not reach the target MOE. If the dust-loader wears baseline clothing plus coveralls and chemical-resistant gloves, the calculated total MOE (dermal and inhalation) is 670, which does not exceed HED's level of concern. However, the combined activity of loading and applying is usually done by the same individual handler, and no reasonable surrogate for the activity of operating the power duster is available in PHED. Supplemental information is available for consideration in addressing the dust loading/applying activity.

Information on the malathion use pattern on dates was provided by the OPP's Biological and Economic Analysis Division (BEAD communication, March 14, 2001). According to BEAD information, 3500 acres of deglet dates are grown in California, 80% of which are treated with malathion. Date bunches are treated by a person on a cherry-picker, 60 feet up in the canopy of the tree, using a hand-held power duster to apply a maximum of 4.25 lb ai/acre. BEAD estimates that one person could treat 5 acres in an 8-hour day. One person loads/applies and one person drives the truck-mounted cherry-picker.

A study by Krieger and Dinoff, "Malathion Deposition, Metablolic Clearance, and Cholinesterase Status of Date Dusters and Harvesters in California," in *Arch. Environ. Contam. Toxicol.* Volume 38, Pages 456-553 (2000) provides estimates of occupational exposure from the use of malathion to treat dates.

The study used urinary clearance of alkyl phosphates and malathion mono- and di-acids as indicators of malathion exposure. Loaders/applicators were monitored over full work shifts on successive days, wearing coveralls, dust masks, hats and gloves. Application rates ranged from 1 to 4 lbs ai/acre. For loader/applicators, the estimated daily doses ranged from 0.4 to 1 mg/kg/day. Because these are total doses, and no airborne measurements were taken, the contributions to dose from dermal versus inhalation are not known. If all the dose is ascribed to the dermal route (NOAEL = 50 mg/kg/day), the **MOE for loaders/applicators ranges from 50 to 125.** The range of MOEs for loader/applicators pose a concern for the Agency at the lower end. Because workers were already wearing coveralls, gloves and dust/mist respirators, there are no additional mitigation strategies that would seem applicable to to address the exposures that did not reach the target MOE of 100. It is not expected that engineering controls would be applicable to the operator of the power-duster.

It should be noted that the Krieger and Dinoff study has not received a primary review by EPA, and therefore, even though the estimated risks described above are quantitative, they should be considered only as a screen until this study is subjected to a more thorough analysis by Agency scientists, especially those with expertise in biomonitoring and metabolism studies.

Data Quality and Confidence, and Data Gaps in Assessment.

HED has overall confidence that the calculated occupational handler risks are not underestimated, since a number of upper range input variables were used in the calculations (e.g., maximum application rates and durations of exposure). Also, PHED unit exposure data, when extrapolated to cover exposure from high volume applications (e.g., 1200 acres/day for aerial treatment of cotton and corn), likely represent a conservative input into the estimates of risk

No data exist for use in assessing the activity of grape root dipping. Also, data gaps exist for the use of power dusters in general, and, in particular, to this assessment for their use in applying malathion dusts to dates and stored grain.

As described earlier, a published study, "Malathion Deposition, Metabolite Clearance, and Cholinesterase Status of Date Dusters and Harvesters in California," (2000) authored by Krieger and Dinoff. *Arch. Environ. Contam. Toxicol.* Volume 38, Pages 546-553, was submitted by the USDA for consideration in this malathion assessment. The study reports estimated daily exposure doses of from 0.4 - 1.0 mg malathion/kg/day (i.e., MOEs from 50 to 125, if the total dose is attibuted to dermal exposure) for handlers who load/operate power dusters to treat dates with malathion 5% dust. While these MOEs bracket the target MOE of 100 for cholinesterase inhibition, the extent to which inhalation exposure contributed to the total dose is not known. Since the inhalation MOE must equal or exceed 1000 (for histopathologic lesions), the results of this study do not present a definitive basis upon which to assess power duster loader/operators in this handler section, but should be viewed as supplemental information upon which to base a risk management decision.

2.2 Occupational Postapplication Exposures and Risks

EPA has determined that there are potential short- and intermediate-term occupational postapplication exposures to individuals entering treated fields and contacting malathion residues on plant surfaces. Only postapplication dermal exposure has been assessed because postapplication inhalation exposure is expected to be negligible. Workers are expected, generally, to be performing activities (harvesting or non-harvesting) in malathion-treated fields for more than 30 consecutive workdays in a growing season (i.e., short- and intermediate-term exposure potential), with some fields receiving repeat malathion applications at 7-10 day intervals. Because of the seasonal nature of malathion use, a long-term exposure scenario is not expected for field workers. Mushroom houses are a special case, where the indoor, nearly year long treatment and harvesting of multiple crop cycles result in the potential for mushroom house workers to experience long-term exposure to malathion (i.e. $\geq$180 days).

2.2.1 Postapplication Exposure Scenarios, Data, and Assumptions for Occupational Use

Postapplication exposure scenarios assessed for malathion were developed from the revised HED Exposure Science Advisory Council Policy (Policy 003 - revised August 7, 2000) on Agricultural Transfer Coefficients. Transfer coefficients are based primarily on data submitted by the Agricultural Reentry Task Force (ARTF) to the Agency or from published literature studies. Data from these studies are proprietary and compensation issues with ARTF may need to be addressed. The crop groupings and activities were based in large part on the ARTF Scoping Survey. Occupational postapplication exposure scenarios, including crops, range of transfer coefficients and range of application rates used in this assessment are summarized in Table 10 (for EC, WP and RTU formulations) and Table 11 (for ULV formulation).

Table 10. Crop Groupings: Selected Transfer Coefficients, Treated Crops, and Rates (EC, WP and RTU formulations)

[redacted]	[redacted]	[redacted]	[redacted]	[redacted]
Berry, low	1500 400 - 1,800	400 400 - 1,800	Blueberries (lowbush), Strawberries	1.25 to 2
Bunch / bundle	2000 1,346 - 2,308	100 TBD	Hops, Dates	0.63 to 4.25
Field / row crops, low / medium	2500 486 - 2,760	100 TBD	Alfalfa, Barley, Clover, Cotton, Flax, Grasses (forage and hay grass), Lespedeza, Lupine, Mint, Oats, Peas (green), Rice, Rye, Vetch, Wheat (spring), Wheat (winter), Wild rice	0.5 to 2.5
Field / row crops, tall	1000 418 - 1,980	100 TBD	Corn (all types), Sorghum	1.25
Trees, fruit, deciduous	3000 1,421 - 4,393	1000 197 - 2,302	Apples, Apricots, Cherries, Figs, Nectarines, Peaches, Pears, Quince	1.25 to 3.75
Trees, fruit, evergreen	3000 2,177 - 3,688	1000 197 - 2,302	Avocados, Grapefruit, Guava, Kumquat, Lemons, Lime, Mangos, Oranges, Papaya, Tangelo, Tangerines	1.25 to 6.25
Trees, nut	2500 1,121 - 4,929	500 197 - 2,302	Chestnut, Macadamia nuts, Pecans, Walnuts	0.94 to 5
Unassigned	N/A	N/A	Mushrooms	1.7
Vegetable, cucurbit	2500 486 - 2,760	500 486 - 2,760	Cantalope, Chayote fruit, Cucumbers, Melons, Pumpkin, Squash (summer), Squash (winter), Watermelon	1 to 1.88
Vegetable, fruiting	1000 364 - 1,908	500 486 - 2,760	Eggplant, Okra, Peppers (bell), Peppers (chili), Tomatoes (fresh), Tomatoes (processed)	1.5 to 3.43
Vegetable, head and stem Brassica	5000 2,862 - 7,584	2000 1,672 - 8,147	Broccoli, Broccoli raab, Brussel sprouts, Cabbage, Cauliflower, Kohlrabi, Mustard greens	1.25

Vegetable, leafy	2500 486 - 2,760	500 486 - 2,760	Celery, Collards, Dandelion, Endive (escarole), Kale, Lettuce, Parsley, Spinach, Swiss chard, Watercress	1.25 to 2
Vegetable, root	2500 486 - 2,760	300 140 - 290	Beets (table), Carrots, Chayote root, Garlic, Horseradish, Leeks, Onion, Parsnip, Potatoes, Radish, Rutabaga, Salsify, Shallots, Sweet potatoes, Turnips, Yams	1.25 to 1.56
Vegetable, stem / stalk	1000 364 - 1,908	300 140 - 290	Asparagus, Pineapple	1.25 to 5
Vine / trellis (w/ girdling)	5000 TBD	500 197 - 2,302	Boysenberries, Grapes (table and raisin)	1.88 to 2
Vine / trellis (w/o girdling)	5000 TBD	500 197 - 2,302	Blackberries, Blueberries (highbush), Dewberry, Grapes (juice and wine), Loganberry, Passion fruit, Raspberries	1.25 to 2

Flowers, cut	400 TBD	110 TBD	Ornamentals (flowers, shrubs, flowering plants, nursery stock, and wood plants)	2.5
Trees, fruit, evergreen	3000 2,177 - 3,688	1000 197 - 2,302	Pine trees (Pine seed orchards, Christmas trees, Slash pine plantations, shrubs, shade trees, forest trees)	2.5

2.2.2 Basis and Approach for Assessment of Postapplication Scenarios

Malathion is used in a wide variety of agricultural crops, but only 6 dislodgeable foliar residue studies were submitted that meet current Agency guidelines for sampling techniques and data quality. Postapplication exposures in this assessment were based on the chemical-specific residue dissipation rates determined from these studies, along with surrogate transfer coefficients from Agency's interim transfer coefficient policy developed by HED's Science Advisory Council for Exposure using proprietary data from the Agricultural Re-entry Task Force (ARTF) database (policy # 3.1 , August 17, 2000).

The chemical-specific dissipation data used in this current assessment were generated in studies completed by the ARTF as part of its data generation effort. These studies were conducted on grapes, apples, squash, blackberries and nursery stock. Data from these studies were extrapolated to other crops based on the nature of the crop group and application method. For example, the apple data were used to calculate risks for all tree crops because airblast (which was used in the apple study) would be the application method of choice for tree crops and the plant canopies are similar (i.e., can impact light and precipitation levels which in turn impact DFRs). When the Agency extrapolated the available DFR data to other crops, it adjusted the data for differences in application rate using a simple proportional approach. This approach seems to be the most appropriate given the data which are available. This approach is commonly used in Agency postapplication risk assessments. A more complete description of the DFR data used in this assessment is provided below.

Postapplication Studies: A total of six studies are described in this section. The studies were all conducted by the ARTF for use in defining generic transfer coefficients. Malathion is one of the compounds that was selected by the ARTF as a surrogate chemical for its efforts. These studies quantified residue dissipation and exposure during scouting in grapes, harvesting in grapes, apples, squash and blackberries, and pruning nursery stock. The DFR component of those studies has been extracted for chemical-specific use in this risk assessment. The studies which have been used in this assessment are identified below followed by a brief summary of each:

MRID 450059-10. ARTF Study No. ARF023. "Determination of Dermal and Inhalation Exposure to Reentry Workers During Scouting in Grapes," November 1999.

This study was conducted with Malathion 57 EC® for the purpose of establishing transfer coefficients. Only the dislodgeable foliar residue (DFR) portion of the study was used in the postapplication assessment, and is summarized here. Two applications of malathion were made at seven days apart, to test plots in the San Joaquin Valley of California, by vertical boom sprayer at a rate of 1 lb ai/A in a spray volume of 210 gal/A. Samples were collected prior to the first application, and on day 0 (after spray was dry). Following the second application, DFR samples were collected on day 0 (after spray was dry), and then at 1, 2, 3, 4, 5, 6, 7, 14 and 21 days after application. On the sampling days, triplicate samples were collected across the two test subplots and single samples from a separate untreated control plot. Forty leaf punches were obtained for

each sample with a Birkestrand leaf punch, resulting in 400 cm^2 of leaf surface (both sides) per sample. Residues on leaf discs were dislodged with 0.01% Aerosol OT solution. The limit of quantitation (LOQ) in this study was 2.0 ug/sample or 0.005 ug/cm^2. Field recovery values were within the acceptable range. No significant rainfall event was evident that might affect results. Results of the statistical analysis of the data are presented in the table below.

Grape DFR Dissipation Data (MRID 450059-10)					
Location	App. Rate in Study (lb ai/A)	Corr. Coeff. (adjust. R^2)	Slope of Semilog Regression	Day 0 Conc. (ug/cm^2)	% Dissipation/Day
CA	1.0	0.87	-0.3533906	1.39	30

These residue data were extrapolated in the postapplication assessment of malathion to cover the following currently labelled crops: grapes, hops and passion fruit.

MRID 454919-01. ARTF Study No. ARF048. "Determination of Dermal and Inhalation Exposure to Reentry Workers During Harvesting in Wine Grapes," March 2001.

This study was conducted with Malathion 57 EC® for the purpose of establishing transfer coefficients. Only the dislodgeable foliar residue (DFR) portion of the study was used in the postapplication assessment, and is summarized here. Two applications of malathion were made at seven days apart, to test plots in Sanger, California, by vertical boom sprayer at a rate of 0.93 lb ai/A in a spray volume of 218 gal/A. Samples were collected just before the first application and on day 0 (after spray was dry). Following the second application, DFR samples were collected on day 0 (after spray was dry), and then at 1, 2, 3, 4, 5, 6, 7, 10 and 14 days after application. On the sampling days, triplicate samples were collected across the two test subplots and single samples from a separate untreated control plot. Forty leaf punches were obtained for each sample with a Birkestrand leaf punch, resulting in 400 cm^2 of leaf surface (both sides) per sample. Residues on leaf discs were dislodged with 0.01% Aerosol OT solution. The limit of quantitation (LOQ) in this study was 2.0 ug/sample or 0.005 ug/cm^2. No significant rainfall event was evident that might affect results. Results of the statistical analysis of the data are presented in the table below.

Wine Grape DFR Dissipation Data (MRID 454919-01)					
Location	App. Rate in Study (lb ai/A)	Corr. Coeff. (adjust. R^2)	Slope of Semilog Regression	Day 0 Conc. (ug/cm^2)	% Dissipation/Day
CA	0.93	0.92	-0.4367956	0.57	35

These residue data would cover grapes, hops and passion fruit, however, they were not extrapolated in the postapplication assessment of malathion. Data from the grape study, MRID 450059-10, were used because they represent a more conservative surrogate screen.

MRID 451382-02. ARTF Study No. ARF025. "Determination of Dermal and Inhalation Exposure to Reentry Workers During Harvesting in Apples," January 2000.

This study was conducted with Malathion 57 EC® for the purpose of establishing transfer coefficients. Only the dislodgeable foliar residue (DFR) portion of the study was used in the postapplication assessment, and is summarized here. Two applications of malathion were made at ten days apart, to test plots in Orefield, Pennsylvania, by airblast sprayer at a rate of 1.25 lb ai/A in a spray volume of 125 gal/A. Samples were collected two days before the first application and on day 0 (after spray was dry). Following the second application, DFR samples were collected on day 0 (after spray was dry), and then at 1, 2, 3, 5, 6, 7, and 15 days after application. On the sampling days, triplicate samples were collected across the two test subplots and single samples from a separate untreated control plot. Forty leaf punches were obtained for each sample with a Birkestrand leaf punch, resulting in 400 cm^2 of leaf surface (both sides) per sample. Residues on leaf discs were dislodged with 0.01% Aerosol OT solution. The limit of quantitation (LOQ) in this study was 2.0 ug/sample or 0.005 ug/cm^2. A rainfall event between day 3 and 4 following application significantly lowered DFR values. Results of the statistical analysis of the data are presented in the table below.

Apple DFR Dissipation Data (MRID 451382-02)					
Location	App. Rate in Study (lb ai/A)	Corr. Coeff. (adjust. R^2)	Slope of Semilog Regression	Day 0 Conc. (ug/cm^2)	% Dissipation/Day
PA	1.25	0.70	-0.468671	2.65	37

These residue data were extrapolated in the postapplication assessment of malathion to cover the following currently labelled crops: apple, apricot, avocado, cherry, chestnut, fig, grapefruit, guava, kumquat, lemon, lime, macadamia nut, mango, nectarine, orange, papaya, peach, pear, pecan, quince, tangelo, tangerine, walnut, pine seed orchards, Christmas tree plantations, shade trees, and forest trees.

MRID 454919-02. ARTF Study No. ARF049. "Determination of Dermal and Inhalation Exposure to Reentry Workers During Harvesting in Summer Squash," May 2001.

This study was conducted with Malathion 57 EC® for the purpose of establishing transfer coefficients. Only the dislodgeable foliar residue (DFR) portion of the study was used in the postapplication assessment, and is summarized here. Two applications of malathion were made at seven days apart, to test plots in Porterville, California, by tractor-mounted boom sprayer at a rate of 0.95 lb ai/A in a spray volume of 20 gal/A. Samples were collected on the day before the first application and on day 0 (after spray was dry). Following the second application, DFR samples were collected on day 0 (after spray was dry), and then at 1, 2, 3, 4, 5, 6, and 7 days after application. On the sampling days, triplicate samples were collected across the two test subplots and single samples from a separate untreated control plot. Forty leaf punches were obtained for each sample with a Birkestrand leaf punch, resulting in 400 cm^2 of leaf surface (both sides) per

sample. Residues on leaf discs were dislodged with 0.01% Aerosol OT solution. The limit of quantitation (LOQ) in this study was 2.0 ug/sample or 0.005 ug/cm^2. No significant rainfall events were evident to affect the results. Results of the statistical analysis of the data are presented in the table below.

Squash DFR Dissipation Data (MRID 454919-02)					
Location	App. Rate in Study (lb ai/A)	Corr. Coeff. (adjust. R^2)	Slope of Semilog Regression	Day 0 Conc. (ug/cm^2)	% Dissipation/Day
CA	0.95	0.83	-0.583225	3.95	44

These residue data were extrapolated in the postapplication assessment of malathion to cover the following currently labelled crops: alfalfa, asparagus, barley, beets, broccoli, broccoli-raab, brussels sprouts, cabbage, carrot, cantaloupe, cauliflower, celery, chayote root, chayote fruit, clover, collards, corn, cotton, cucumber, dandelion, eggplant, endive, flax, garlic, grasses (hay, forage), horseradish, kale, kohlrabi, leeks, lespedeza, lettuce, lupine, melon, mint, mushroom, mustard greens, oats, okra, onion, parsley, parsnip, peas, pepper, potato, pumpkin, radish, rice, rutabaga, rye, salsify, shallots, sorghum grain, spinach, squash, sweet potato, Swiss chard, tomato, turnip, vetch, watercress, watermelon, wheat, wild rice and yam.

MRID 451382-01. ARTF Study No. ARF020. "Determination of Dermal and Inhalation Exposure to Reentry Workers During Hand-Harvesting in Blackberries," January 2000.

This study was conducted with Malathion 57 EC® for the purpose of establishing transfer coefficients. Only the dislodgeable foliar residue (DFR) portion of the study was used in the postapplication assessment, and is summarized here. Two applications of malathion were made at seven days apart, to test plots in Mount Angel, Oregon, by airblast sprayer at a rate of 1.9 lb ai/A in a spray volume of 90 gal/A. Samples were collected on the day before the first application and on day 0 (after spray was dry). Following the second application, DFR samples were collected on day 0 (after spray was dry), and then at 1, 2, 3, 4, 5, 6, 7 and 14 days after application. On the sampling days, triplicate samples were collected across the two test subplots and single samples from a separate untreated control plot. Eighty leaf punches were obtained for each sample with a Birkestrand leaf punch, resulting in 400 cm^2 of leaf surface (both sides) per sample. Residues on leaf discs were dislodged with 0.01% Aerosol OT solution. The limit of quantitation (LOQ) in this study was 2.0 ug/sample or 0.005 ug/cm^2. No rainfall events were evident to affect the results. Results of the statistical analysis of the data are presented in the table below.

Blackberry DFR Dissipation Data (MRID 451382-01)					
Location	App. Rate in Study (lb ai/A)	Corr. Coeff. (adjust. R^2)	Slope of Semilog Regression	Day 0 Conc. (ug/cm^2)	% Dissipation/Day
OR	1.9	0.91	-0.3923051	1.24	32

These residue data were extrapolated in the postapplication assessment of malathion to cover the following currently labelled crops: blackberry, blueberry, boysenberry, dewberry, loganberry, pineapple, raspberry and strawberry.

MRID 454695-01. ARTF Study No. ARF043. "Determination of Dermal and Inhalation Exposure to Reentry Workers During Pruning in Nursery Stock," January 2000.

This study was conducted with Malathion 57 EC® for the purpose of establishing transfer coefficients. Only the dislodgeable foliar residue (DFR) portion of the study was used in the postapplication assessment, and is summarized here. A single application of malathion was made to test plots of assorted citrus trees in Yuma, Arizona, by commercial boom sprayer at a rate of 1.3 lb ai/A in a spray volume of 47 gal/A. Samples were collected on the day before application, on day 0 (after spray was dry), and then at 1, 2, 3, 4, 5, 6, 7 and 14 days after application. On the sampling days, triplicate samples were collected across the two test subplots and single samples from a separate untreated control plot. Forty leaf punches were obtained for each sample with a Birkestrand leaf punch, resulting in 400 cm^2 of leaf surface (both sides) per sample. Residues on leaf discs were dislodged with 0.01% Aerosol OT solution. The limit of quantitation (LOQ) in this study was 2.0 ug/sample or 0.005 ug/cm^2. No rainfall events were evident to affect the results. Results of the statistical analysis of the data are presented in the table below.

Nursery Stock DFR Dissipation Data (MRID 454695-01)					
Location	App. Rate in Study (lb ai/A)	Corr. Coeff. (adjust. R^2)	Slope of Semilog Regression	Day 0 Conc. (ug/cm^2)	% Dissipation/Day
AZ	1.3	0.88	-0.4140081	2.63	34

These residue data were extrapolated in the postapplication assessment of malathion to cover all currently labelled ornamental crops, including nusery stock, shrubs and cut flowers.

It should be noted that this assessment of the potential postapplication exposure reflects residue of malathion *per se*. Information specific to the potential formation of malaoxon following uses subject to this tolerance reassessment action has not been submitted. Monitoring data used in the assessment of malathion bait spray in the California medfly eradication program (Bradman, M.A.,et al., 1994) indicates the postapplication formation of the oxidative breakdown product, malaoxon, at levels an order of magnitude less than the parent compound on plant surfaces. Although aware of the possible formation of malaoxon following the uses subject to this reregistration action, there is insufficient information currently available to perform a quantitative exposure assessment without a large degree of uncertainty. Therefore, an assessment of the potential postapplication exposure to malaoxon has not been performed, and in order to do so would require the results from residue dissipation studies that specifically measured for malaoxon.

2.2.3 Occupational Postapplication Exposure and Risk Estimates

Postapplication exposure and risk assessments were performed for the crop groupings, application rates, activities and transfer coefficients summarized in Tables 10 and 11 above. The results of these assessments are summarzed in Tables 13 and 14 below, with details regarding the reentry exposure levels for specific use rates and crop sites presented in Attachment 2 to this document.

The equations used for the calculations in Tables 13 and 14 are presented below:

$$DFR\left(\frac{\mu g}{cm^2}\right) = AR\left(\frac{lb\ ai}{acre}\right) \times CF\left(\frac{\mu g/cm^2}{lb\ ai/acre}\right) \times F \times (1 - DR)^t$$

Where:

DFR	=	Dislodgeable foliar residue ($\mu g/cm^2$),
AR	=	Application rate (lb ai/acre),
CF	=	Conversion factor (11.2 $\mu g/cm^2$ per lb ai/acre),
F	=	Fraction retained on foliage (%),
DR	=	Daily dissipation rate (%),
t	=	Days after treatment.

$$\text{Dose (mg/kg/day)} = \frac{(DFR\ (\mu g/cm^2) \times Tc\ (cm^2/hr) \times CF\ (0.001\ mg/\mu g) \times ED\ (hr/day)) \times Abs\ (\%/100)}{BW\ (kg)}$$

Where:

Tc	=	Transfer coefficient (cm^2/hr),
CF	=	Conversion factor (0.001 $mg/\mu g$),
Abs	=	Absorption (10% dermal absorption; applies only to long-term exposure)
ED	=	Exposure duration (8 hours worked per day), and
BW	=	Body weight (70 kg).

MOE = NOAEL (mg/kg/day) ÷ Dose (mg/kg/day

Where:

NOAEL= 50 mg/kg/day (short and intermediate-term) or 2.4 mg/kg/day (long-term)
Dose = Calculated dose.

2.2.4 Summary of Occupational Postapplication Risks, Data Gaps, and Confidence in Exposure and Risk Estimates

Postapplication Worker Risks

Tables 13 (EC, WP and RTU formulations) and 14 (ULV formulations) below, present, by crop grouping, the range of "days after treatment" at which the dermal MOEs reach or exceed the target of 100. For each crop grouping, the range of "days after treatment" are presented for a range of activities from "very low" contact (e.g., propping fruit trees), to "very high" contact (e.g., thinning fruit trees). As seen earlier with handlers, postapplication risks also vary significantly according to application rate. Most "low and very low" contact activities reach the target MOE on the day of application. Even for "high and very high" contact activities, the range is from 0 to 6 days after treatment. Attachment 2 presents the detailed results of the postapplication assessment for each crop, activity and application rate.

The existing REI established under the Worker Protection Standard (WPS) is 12 hours. Occupational postapplication risks for crop/activity/application rate combinations that lead to REI determinations of more than "day 0," exceed the WPS-determined REI.

The postapplication assessment for two specific malathion use sites are presented separately below, because of the need to describe additional information and basis for the assessment.

- **Mushroom Houses**

Malathion is applied to commercial mushroom house beds as often as twice per week from approximately April to December to control flies. The application is to vacant portions of beds and not directly to the growing mushrooms. Postapplication exposure from contact with treated beds is expected to be minimal until growing mushrooms are cut and harvested. Because both treatment and postapplication activities occur for more than 180 continuous days, short- and intermediate-term exposure is expected, and long-term exposure is believed to be possible.

The transfer coefficient used here (i.e., 2500 cm^2/hour) is from the HED Science Advisory Council for Exposure Policy # 003 (May 7, 1998), and only covers "high" contact activities (i.e., cutting, harvesting, sorting and packing). Transfer coefficients from the ARTF do not include those for activities involved in commercial mushroom production.

Using the **short-, and intermediate-term** dermal endpoint NOAEL of 50 mg/kg/day, results in an MOE that equals or exceeds the target MOE of 100 (i.e., MOE = 141) for high contact activities on the **2nd day following application** of malathion to mushroom beds at a rate of 1.7 lb ai/acre.

The **long-term** dermal NOAEL for malathion is 2.4 mg/kg/day, from a two-year feeding study. A dermal equivalent dose (using a 10% dermal absorption factor) of 24 mg/kg/day was used in the estimation of long-term postapplication risk. The resulting risk (i.e., MOE = 119) exceeds the target MOE of 100 for high contact activities on the **3rd day following application**.

- **Dates**

Information on the malathion use pattern on dates was provided by the OPP's Biological and Economic Analysis Division (BEAD communication, March 14, 2001). According to BEAD, three to five applications are made starting in August, and up to 21 days before harvest at the end of October, with typically 2 - 3 weeks between applications. The only activities undertaken following application are irrigation and discing on ground, which currently occurs at 24 hours postapplication. No residue dissipation data are available for malathion on dates. A study by Krieger and Dinoff, "Malathion Deposition, Metablolic Clearance, and Cholinesterase Status of Date Dusters and Harvesters in California," in *Arch. Environ. Contam. Toxicol.* Volume 38, Pages 456-553 (2000) presented occupational postapplication exposure estimates from harvesting malathion treated dates.

The study used urinary clearance of alkyl phosphates and malathion mono- and di-acids as indicators of malathion exposure. Harvesters were monitored over full work shifts, over a two-day period, wearing baseline clothing, plus gloves and a hat. Monitoring was also conducted for harvesters over a two-week period. Application rates ranged from 1 - 4 lbs ai/acre. For harvesters, the estimated daily dose ranged from 0.001 to 0.3 mg/kg/day. **For harvesters the corresponding MOEs range from 170 to 50,000.** These values would indicate that risks to harvesters are well above the target MOE of 100 and would not pose a concern to the Agency. However, it should be kept in mind that the monitored workers were wearing gloves, which are not a requirement for postapplication workers.

For comparative purposes, the postapplication exposure also was estimated using the ARTF transfer coefficient (Tc) for "Bunch/bundle" crops (i.e., Tc = 2000 for harvesting, pruning, thinning and weeding; from ARF024). From this analysis, the MOE on "day 0" is 37. It is not until the 3rd day following application that the risk reaches or exceeds the target MOE of 100 (i.e., MOE = 110) for the activity of harvesting dates. However, for activities which are discribed as the only activities occurring within 24 hours of treatment (i.e., discing and irrigation) the appropriate transfer coefficient of 100 (for low contact activities), yields an MOE of 740 on day 0 following application, which does not exceed HED's level of concern. More details on the postapplication assessment for dates are found in Attachment 2 of this document.

Table 13. Summary of 'Days After Treatment' to Reach the Target MOE for Intermediate-term Exposure (EC, WP and RTU formulations)

Berry, low	Blueberries (lowbush), Strawberries	1.25 - 2	N/A	0	N/A	0	N/A
Bunch / bundle	Hops, Dates	0.63 - 4.25	N/A	0	0 - 2	0 - 3	N/A

Data Quality, Confidence and Data Gaps in Assessment

Transfer coefficients used are believed to be the best currently available for the assessment of malathion postapplication exposure potential. The use of maximum application rates for each crop will help prevent an underestimation of risks.

Appropriate chemical-specific DFR studies were available to determine postapplication risks for some of the major crop groups: tree crops, nursery crops, low/medium field row crops, vine/trellis and berries. All individual crops were addressed by using the data from these studies, although in some cases data were used for crops that would better be represented by malathion crop-specific studies. For example, data from the malathion DFR study on squash was used to cover crops such as alfalfa and clover, for which the squash data were the best available fit.

HED's revised policy 003 for transfer coefficients only quantitatively addresses risks where the transfer coefficient model is appropriate (i.e., where foliar contact is known to exist). There are many kinds of potential exposure pathways that do not involve foliar contact that have not been addressed in this risk assessment (as defined in policy 003, refer to that document for a complete list). The scenarios include:

- Transplanting many crops including in the ornamental and forestry industry;
- Thinning some crops such as hops;
- Hand weeding some crops such as wheat;
- Various operations with Christmas trees such as pruning or baling;
- Various operations with nut production such as sweeping for harvest; and
- Some partially mechanized operations that also involve human contact (e.g., cotton harvesting where module builders and trampers are used, see below).

The latter two scenarios involve mechanical operations. Mechanized practices can be divided into fully mechanized activities that meet the definition of "No contact" in the Agency's Worker Protection Standard (WPS) and mechanically assisted practices with potential for exposure.

In the case of fully mechanized activities, the Agency addresses potential exposures by allowing early entry as described in the WPS:

"A worker may enter a treated area during a restricted-entry interval if the agricultural employer assures that both of the following are met: (1) The worker will have no contact with anything that has been treated with the pesticide to which the restricted-entry interval applies including, but not limited to, soil, water, air, or surfaces of plants; and (2) no such entry is

allowed until any inhalation exposure level listed in the labeling has been reached or any ventilation criteria established by § 170.110 (c)(3) or in the labeling have been met."

The Agency also acknowledges that there is some potential for exposure because individuals engaged in fully mechanized activities have short-term excursions from the protected area for various reasons (e.g., unclogging machinery or equipment inspection for breakage). In these cases, the WPS § 170.112(c) *Exception for short-term activities* applies.

The postapplication assessment in this document sometimes includes risk estimates for high contact activities such as hand-harvesting for crops which are rarely hand-harvested (e.g., field row crops). The Agency recognizes that REIs should rarely be based on such risks, but includes them in its assessment for the limited, but possible occurrence of such scenarios.

[1]Baseline dermal unit exposures represent long pants, long sleeved shirts, shoes, and socks. Values are reported in the PHED Surrogate Exposure Guide dated August 1998 or are from data submitted by the Outdoor Residential Exposure Task Force dated May 2000.

[2]Baseline inhalation unit exposures represent no respirator. Values are reported in the PHED Surrogate Exposure Guide dated August 1998 or are from data submitted by the Outdoor Residential Exposure Task Force dated May 2000.

[3]Crops and use patterns are from submissions by the primary producer, Cheminova, or found in various sources including LUIS and various labels

[4]Application rates are based primarily on maximum rates used in residue field trial studies and supported by the primary producer, Cheminova, or found in various sources including LUIS and various labels. Most application rates upon which the analysis is based are presented as lb ai/A. In some cases, the application rate is based on applying a solution at concentrations specified by the label (i.e., presented as lb ai/gallon).

[5]Amount treated is based on the area or gallons that can be reasonably applied in a single day for each exposure scenario of concern based on the application method and formulation/packaging type. (Standard EPA/OPP/HED values).

[6]Dermal dose (mg/kg/day) = [unit exposure (mg/lb ai) * Dermal absorption (100%) * Application rate (lb ai/acre or lb ai/gallon) * Daily area treated (acres or gallons)] / Body weight (70 kg).

[7]Dermal MOE = Dermal NOAEL (50 mg/kg/day) / Daily Dermal Dose. Target Dermal MOE is 100.

[8]Inhalation dose (mg/kg/day) = [unit exposure (ug/lb ai) * 0.001 mg/ g unit conversion * Inhalation absorption (100%) * Application rate (lb ai/acre or lb ai/gallon) * Daily area treated (acres or gallons)] / Body weight (70 kg).

[9]Inhalation MOE = Inhalation LOAEL (25.8 mg/kg/day) / Daily Inhalation Dose. Target Inhalation MOE is 1000.

Short Term and Intermediate-term with PPE 1 (Single Layer Protection, Gloves, No Respirator) for Malathion

[1]PPE1 dermal unit exposures represent long pants, long sleeved shirts, and chemical-resistant gloves. Values are reported in the PHED Surrogate Exposure Guide dated August 1998 or are from data submitted by the Outdoor Residential Exposure Task Force dated May 2000.

[2]PPE1 inhalation unit exposures represent no respirator. Values are reported in the PHED Surrogate Exposure Guide dated August 1998 or are from data submitted by the Outdoor Residential Exposure Task Force dated May 2000.

[3]Crops and use patterns are from submissions by the primary producer, Cheminova, or found in various sources including LUIS and various labels

[4]Application rates are based primarily on maximum rates used in residue field trial studies and supported by the primary producer, Cheminova, or found in various sources including LUIS and various labels. Most application rates upon which the analysis is based are presented as lb ai/A. In some cases, the application rate is based on applying a solution at concentrations specified by the label (i.e., presented as lb ai/gallon).

[5]Amount treated is based on the area or gallons that can be reasonably applied in a single day for each exposure scenario of concern based on the application method and formulation/packaging type. (Standard EPA/OPP/HED values).

[6]Dermal dose (mg/kg/day) = [unit exposure (mg/lb ai) * Dermal absorption (100%) * Application rate (lb ai/acre or lb ai/gallon) * Daily area treated (acres or gallons)] / Body weight (70 kg).

[7]Dermal MOE = Dermal NOAEL (50 mg/kg/day) / Daily Dermal Dose. Target Dermal MOE is 100.

[8]Inhalation dose (mg/kg/day) = [unit exposure (ug/lb ai) * 0.001 mg/ g unit conversion * Inhalation absorption (100%) * Application rate (lb ai/acre or lb ai/gallon) * Daily area treated (acres or gallons)] / Body weight (70 kg).

[9]Inhalation MOE = Inhalation LOAEL (25.8 mg/kg/day) / Daily Inhalation Dose. Target Inhalation MOE is 1000.

Short Term and Intermediate Term Risk with PPE 2 (Single Layer Protection, Gloves, PF5 Respirator) for Malathion

[1]PPE2 dermal unit exposures represent long pants and long sleeved shirts plus chemical-resistant gloves. Values are reported in the PHED Surrogate Exposure Guide dated August 1998 or are from data submitted by the Outdoor Residential Exposure Task Force dated May 2000.

[2]PPE2 inhalation unit exposures represent a dust/mist respirator with a protection factor of 5. Values are reported in the PHED Surrogate Exposure Guide dated August 1998 or are from data submitted by the Outdoor Residential Exposure Task Force dated May 2000.

[3]Crops and use patterns are from submissions by the primary producer, Cheminova, or found in various sources including LUIS and various labels.

[4]Application rates are based primarily on maximum rates used in residue field trial studies and supported by the primary producer, Chemiova, or found in various sources including LUIS and various labels. Most application rates upon which the analysis is based are presented as lb ai/A. In some cases, the application rate is based on applying a solution at concentrations specified by the label (i.e., presented as lb ai/gallon).

[5]Amount treated is based on the area or gallons that can be reasonably applied in a single day for each exposure scenario of concern based on the application method and formulation/packaging type. (Standard EPA/OPP/HED values).

[6]Dermal dose (mg/kg/day) = [unit exposure (mg/lb ai) * Dermal absorption (100%) * Application rate (lb ai/acre or lb ai/gallon) * Daily area treated (acres or gallons)] / Body weight (70 kg).

[7]Dermal MOE = Dermal NOAEL (50 mg/kg/day) / Daily Dermal Dose. Target Dermal MOE is 100.

[8]Inhalation dose (mg/kg/day) = [unit exposure (ug/lb ai) * 0.001 mg/ g unit conversion * Inhalation absorption (100%) * Application rate (lb ai/acre or lb ai/gallon) * Daily area treated (acres or gallons)] / Body weight (70 kg).

[a]Inhalation MOE = Inhalation LOAEL (25.8 mg/kg/day) / Daily Inhalation Dose. Target Inhalation MOE is 1000.

Short Term and Intermediate-Term Risk with PPE 3 (Single Layer Protection, Gloves, PF10 Respirator) for Malathion

[1]PPE3 dermal unit exposures represent long pants and long sleeved shirts plus chemical-resistant gloves. Values are reported in the PHED Surrogate Exposure Guide dated August 1998 or are from data submitted by the Outdoor Residential Exposure Task Force dated May 2000.

[2]PPE3 inhalation unit exposures represent an organic-vapor-removing respirator with a protection factor of 10. Values are reported in the PHED Surrogate Exposure Guide dated August 1998 or are from data submitted by the Outdoor Residential Exposure Task Force dated May 2000.

[3]Crops and use patterns are from submissions by the primary producer, Cheminova, or found in various sources including LUIS and various labels.

[4]Application rates are based primarily on maximum rates used in residue field trial studies and supported by the primary producer, Cheminova, or found in various sources including LUIS and various labels. Most application rates upon which the analysis is based are presented as lb ai/A. In some cases, the application rate is based on applying a solution at concentrations specified by the label (i.e., presented as lb ai/gallon).

[5]Amount treated is based on the area or gallons that can be reasonably applied in a single day for each exposure scenario of concern based on the application method and formulation/packaging type. (Standard EPA/OPP/HED values).

[6]Dermal dose (mg/kg/day) = [unit exposure (mg/lb ai) * Dermal absorption (100%) * Application rate (lb ai/acre or lb ai/gallon) * Daily area treated (acres or gallons)] / Body weight (70 kg).

[7]Dermal MOE = Dermal NOAEL (50 mg/kg/day) / Daily Dermal Dose. Target Dermal MOE is 100.

[8]Inhalation dose (mg/kg/day) = [unit exposure (ug/lb ai) * 0.001 mg/ g unit conversion * Inhalation absorption (100%) * Application rate (lb ai/acre or lb ai/gallon) * Daily area treated (acres or gallons)] / Body weight (70 kg).

[9]Inhalation MOE = Inhalation LOAEL (25.8 mg/kg/day) / Daily Inhalation Dose. Target Inhalation MOE is 1000.

Short Term and Intermediate-Term Risk with PPE 4 (Double Layer Protection, Gloves, No Respirator) for Malathion

[1]PPE4 dermal unit exposures represent coveralls worn over long pants and long sleeved shirts plus chemical-resistant gloves. Values are reported in the PHED Surrogate Exposure Guide dated August 1998 or are from data submitted by the Outdoor Residential Exposure Task Force dated May 2000.

[2]PPE4 inhalation unit exposures represent no respirator. Values are reported in the PHED Surrogate Exposure Guide dated August 1998 or are from data submitted by the Outdoor Residential Exposure Task Force dated May 2000.

[3]Crops and use patterns are from submissions by the primary producer, Cheminova, or found in various sources including LUIS and various labels.

[4]Application rates are based primarily on maximum rates usedin residue field trial studies and supported by the primary producer, Cheminova, or found in various sources including LUIS and various labels. Most application rates upon which the analysis is based are presented as lb ai/A. In some cases, the application rate is based on applying a solution at concentrations specified by the label (i.e., presented as lb ai/gallon).

[5]Amount treated is based on the area or gallons that can be reasonably applied in a single day for each exposure scenario of concern based on the application method and formulation/packaging type. (Standard EPA/OPP/HED values).

[6]Dermal dose (mg/kg/day) = [unit exposure (mg/lb ai) * Dermal absorption (100%) * Application rate (lb ai/acre or lb ai/gallon) * Daily area treated (acres or gallons)] / Body weight (70 kg).

[7]Dermal MOE = Dermal NOAEL (50 mg/kg/day) / Daily Dermal Dose. Target Dermal MOE is 100.

[8]Inhalation dose (mg/kg/day) = [unit exposure (ug/lb ai) * 0.001 mg/ g unit conversion * Inhalation absorption (100%) * Application rate (lb ai/acre or lb ai/gallon) * Daily area treated (acres or gallons)] / Body weight (70 kg).

[9]Inhalation MOE = Inhalation LOAEL (25.8 mg/kg/day) / Daily Inhalation Dose. Target Inhalation MOE is 1000.

Short Term and Intermediate-Term Risk with PPE 5 (Double Layer Protection, Gloves, PF5 Respirator) for Malathion

[1]PPE5 dermal unit exposures represent coveralls worn over long pants and long sleeved shirts plus chemical-resistant gloves. Values are reported in the PHED Surrogate Exposure Guide dated August 1998 or are from data submitted by the Outdoor Residential Exposure Task Force dated May 2000.

[2]PPE5 inhalation unit exposures represent a dust/mist respirator with a protection factor of 5. Values are reported in the PHED Surrogate Exposure Guide dated August 1998 or are from data submitted by the Outdoor Residential Exposure Task Force dated May 2000.

[3]Crops and use patterns are from submissions by the primary producer, Cheminova, or found in various sources including LUIS and various labels.

[4]Application rates are based primarily on maximum rates used in residue field trial studies and supported by the primary procucer, Cheminova, or found in various sources including LUIS and various labels. Most application rates upon which the analysis is based are presented as lb ai/A. In some cases, the application rate is based on applying a solution at concentrations specified by the label (i.e., presented as lb ai/gallon).

[5]Amount treated is based on the area or gallons that can be reasonably applied in a single day for each exposure scenario of concern based on the application method and formulation/packaging type. (Standard EPA/OPP/HED values).

[6]Dermal dose (mg/kg/day) = [unit exposure (mg/lb ai) * Dermal absorption (100%) * Application rate (lb ai/acre or lb ai/gallon) * Daily area treated (acres or gallons)] / Body weight (70 kg).

[7]Dermal MOE = Dermal NOAEL (50 mg/kg/day) / Daily Dermal Dose. Target Dermal MOE is 100.

[8]Inhalation dose (mg/kg/day) = [unit exposure (ug/lb ai) * 0.001 mg/ g unit conversion * Inhalation absorption (100%) * Application rate (lb ai/acre or lb ai/gallon) * Daily area treated (acres or gallons)] / Body weight (70 kg).

[9]Inhalation MOE = Inhalation LOAEL (25 8 mg/kg/day) / Daily Inhalation Dose. Target Inhalation MOE is 1000.

Short Term and Intermediate-Term Risk with PPE 6 (Double Layer Protection, Gloves, PF10 Respirator) for Malathion

[1]Engineering controls dermal unit exposures represent long pants and long sleeved shirts. For mixers and loaders, chemical-resistant gloves are also included. Values are reported in the PHED Surrogate Exposure Guide dated August 1998 or are from data submitted by the Outdoor Residential Exposure Task Force dated May 2000.

[2]Engineering controls inhalation unit exposures represent no respirator. Values are reported in the PHED Surrogate Exposure Guide dated August 1998 or are from data submitted by the Outdoor Residential Exposure Task Force dated May 2000.

[3]Crops and use patterns are from submissions by the primary producer, Cheminova, or found in various sources including LUIS and various labels.

[4]Application rates are based primarily on maximum rates used in residue field trial studies and supported by the primary producer, Cheminova, or found in various sources including LUIS and various labels. Most application rates upon which the analysis is based are presented as lb ai/A. In some cases, the application rate is based on applying a solution at concentrations specified by the label (i.e., presented as lb ai/gallon).

[5]Amount treated is based on the area or gallons that can be reasonably applied in a single day for each exposure scenario of concern based on the application method and formulation/packaging type. (Standard EPA/OPP/HED values).

[6]Dermal dose (mg/kg/day) = [unit exposure (mg/lb ai) * Dermal absorption (100%) * Application rate (lb ai/acre or lb ai/gallon) * Daily area treated (acres or gallons)] / Body weight (70 kg).

[7]Dermal MOE = Dermal NOAEL (50 mg/kg/day) / Daily Dermal Dose. Target Dermal MOE is 100.

[9]Inhalation dose (mg/kg/day) = [unit exposure (ug/lb ai) * 0.001 mg/ g unit conversion * Inhalation absorption (100%) * Application rate (lb ai/acre or lb ai/gallon) * Daily area treated (acres or gallons)] / Body weight (70 kg).
[9]Inhalation MOE = Inhalation LOAEL (25.8 mg/kg/day) / Daily Inhalation Dose. Target Inhalation MOE is 1000.

Summary ofShort Term and Intermediate-Term Handler Risk for Malathion

[1]PPE6 unit exposures represent coveralls worn over long pants and long sleeved shirts plus chemical-resistant gloves and o/v respirator
[1]Engineering controls dermal unit exposures represent long pants and long sleeved shirts. For mixers and loaders

Attachment 2.

Postapplication Risk (EC, WP and RTU formulations)

- 230 pages
- Covers food crop use sites and application rates for emulsifiable concentrates, wettable powders and ready-to-use formulations.
- Detailed exposure and risk information is presented for each individual crop and application rate, including the residue levels, exposure and risk estimates leading up to the "day after treatment" at which the target MOE of 100 is reached.

Note: The "high" and "very high" contact activities assessed for a few crops may rarely occur. During the mitigation phase of the reregistration process, the relevance of REIs estimated for these activities should be discussed.

Table 1. Crop Groupings: Selected Transfer Coefficients, Treated Crops, and Rates (EC, WP and RTU formulations)

Berry, low	1500 400 - 1,800	400 400 - 1,800	Blueberries (lowbush), Strawberries	1.25 to 2
Bunch / bundle	2000 1,346 - 2,308	100 TBD	Dates, Hops	0.63 to 4.25
Field / row crops, low / medium	2500 486 - 2,760	100 TBD	Alfalfa, Barley, Clover, Cotton, Flax, Grasses (forage & hay), Lespedeza, Lupine, Mint, Oats, Peas (dry), Peas (green), Rice, Rye, Vetch, Wheat (spring), Wheat (winter), Wild rice	0.5 to 2.5
Field / row crops, tall	1000 418 - 1,980	100 TBD	Corn (all types), Sorghum	1.25
Trees, fruit, deciduous	3000 1,421 - 4,393	1000 197 - 2,302	Apples, Apricots, Cherries, Figs, Nectarines, Peaches, Pears, Quince	1.25 to 3.75
Trees, fruit, evergreen	3000 2,177 - 3,688	1000 197 - 2,302	Avocados, Grapefruit, Guava, Kumquat, Lemons, Lime, Mangos, Oranges, Papaya, Tangelo, Tangerines	1.25 to 6.25
Trees, nut	2500 1,121 - 4,929	500 197 - 2,302	Chestnut, Macadamia nuts, Pecans, Walnuts	0.94 to 5
Unassigned	N/A	N/A	Mushrooms	1.7 to 2.5
Vegetable, cucurbit	2500 486 - 2,760	500 486 - 2,760	Cantalope, Chayote fruit, Cucumbers, Melons, Pumpkin, Squash (summer), Squash (winter), Watermelon	1 to 1.88
Vegetable, fruiting	1000 364 - 1,908	500 486 - 2,760	Eggplant, Okra, Peppers (bell), Peppers (chili), Tomatoes (fresh), Tomatoes (processed)	1.5 to 3.43

Vegetable, head and stem Brassica	5000 2,862 - 7,584	2000 1,672 - 8,147	Broccoli, Broccoli raab, Brussel sprouts, Cabbage, Cauliflower, Kohlrabi	1.25
Vegetable, leafy	2500 486 - 2,760	500 486 - 2,760	Celery, Collards, Dandelion, Endive, Kale, Lettuce, Mustard greens, Parsley, Spinach, Swiss chard, Watercress	1.25 to 2
Vegetable, root	2500 486 - 2,760	300 140 - 290	Beets (table), Carrots, Chayote root, Garlic, Horseradish, Leeks, Onions (dry), Onions (green), Parsnip, Potatoes, Radish, Rutabaga, Salsify, Shallots, Sweet potatoes, Turnips, Yams	1.25 to 1.56
Vegetable, stem / stalk	1000 364 - 1,908	300 140 - 290	Asparagus, Pineapple	1.25 to 5
Vine / trellis (w/ girdling)	5000 TBD	500 197 - 2,302	Boysenberry, Grapes (table and raisin)	1.88 to 2
Vine / trellis (w/o girdling)	5000 TBD	500 197 - 2,302	Blackberries, Blueberries (highbush), Dewberry, Grapes (juice and wine), Loganberry, Passion fruit, Raspberries	1.25 to 2

1. Crop groupings and transfer coefficients from Science Advisory Council for Exposure: Policy Memo #003.1 'Agricultural Transfer Coefficients', August 17, 2000.
2. Maximum label rates from residue field trial studies and supported by the primary producer, Cheminova, or found on end use product labels.
3. DAT = Days after treatment; DAT0 = On the day of treatment, after sprays have dried; assumed approximately 12 hours.
4. The absorbed dermal dose = DFR (ug/cm2) x TC (cm2/hr) x conversion factor (1 mg/1,000 ug) x exposure time (hrs) x dermal absorption / body weight (kg).
5. MOE = Dermal toxicity endpoint (mg/kg-day)/absorbed dermal dose (mg/kg-d).

3. DAT = Days after treatment; DAT0 = On the day of treatment, after sprays have dried; assumed approximately 12 hours.
4. The absorbed dermal dose = DFR (ug/cm2) x TC (cm2/hr) x conversion factor (1 mg/1,000 ug) x exposure time (hrs) x dermal absorption / body weight (kg).
5. MOE = Dermal toxicity endpoint (mg/kg-day)/absorbed dermal dose (mg/kg-d).

Attachment 2 Cont'd.

Postapplication Risk (EC, WP and RTU formulations)

- 12 pages
- Covers nonfood crop use sites and application rates for emulsifiable concentrates, wettable powders and ready-to-use formulations.
- Detailed exposure and risk information is presented for each individual crop and application rate, including the residue levels, exposure and risk estimates leading up to the "day after treatment" at which the target MOE of 100 is reached.

Note: The "high" and "very high" contact activities assessed for a few crops may rarely occur. During the mitigation phase of the reregistration process, the relevance of REIs estimated for these activities should be discussed.

Table 1. Crop Groupings: Selected Transfer Coefficients, Treated Crops, and Rates

Flowers, cut	400 TBD	110 TBD	Ornamentals (flowers, shrubs, flowering plants, nursery stock, and wood plants)	2.5
Trees, fruit, evergreen	3000 2,177 - 3,688	1000 197 - 2,302	Pine trees (Pine seed orchards, Christmas trees, Slash pine plantations, shrubs, shade trees, forest trees)	2.5

Attachment 2a.

Postapplication Risk (ULV formulations)

- 64 pages
- Covers use sites and application rates for ultra-low volume formulations.
- Detailed exposure and risk information is presented for each individual crop and application rate, including the residue levels, exposure and risk estimates leading up to the "day after treatment" at which the target MOE of 100 is reached.

Note: The "high" and "very high" contact activities assessed for a few crops may rarely occur. During the mitigation phase of the reregistration process, the relevance of REIs estimated for these activities should be discussed.

Table 1. Crop Groupings: Selected Transfer Coefficients, Treated Crops, and Rates (ULV fomulation)

Berry, low	1500 400 - 1,800	400 400 - 1,800	Blueberries (lowbush)	0.76
Field / row crops, low / medium	2500 486 - 2,760	100 TBD	Alfalfa, Barley, Beans (dry), Beans (string), Clover, Cotton, Grasses (forage, hay), Lespedeza, Lupine, Oats, Rice, Rye, Vetch, Wheat (spring), Wheat (winter), Wild rice	0.61 to 1.22
Field / row crops, tall	1000 418 - 1,980	100 TBD	Corn (all types), Sorghum	0.61
Trees, fruit, deciduous	3000 1,421 - 4,393	1000 197 - 2,302	Cherries	1.22
Trees, fruit, evergreen	3000 2,177 - 3,688	1000 197 - 2,302	Grapefruit, Kumquat, Lemons, Lime, Oranges, Tangelo, Tangerine	0.18 to 0.92
Vine / trellis (w/o girdling)	5000 TBD	500 197 - 2,302	Blueberries (highbush)	0.76
