PESTICIDES AND TOXIC SUBSTANCES

MEMORANDUM

SUBJECT: Dietary Exposure Analysis for the Second Round Review of Ethion Using Anticipated Residues

FROM: J. Robert Tomerlin, Ph.D. *JR Tomerlin 8/17/89*
Tolerance Assessment System Staff
HED/SACB (H7509C)

THROUGH: Reto Engler, Ph.D. *for ARB 8/8/89*
Chief, Science Analysis and Coordination Branch
Health Effects Division (H7509C)

TO: Lois Rossi, Chief
Reregistration Branch
Special Review and Reregistration Division (H7508C)

Action Requested

Provide an estimate of dietary exposure to ethion from registered commodities using anticipated residue and per cent crop treated data.

Discussion

1. Toxicology Endpoint: The routine chronic TAS analysis used a reference dose (PADI) of 0.0005 mg/kg body weight/day, based upon a NOEL of 0.05 mg/kg body weight/day and an uncertainty factor of 100 from a 21 day human oral dosing study. This value has been approved by HED (4/19/89) and Agency (5/17/89) reference dose committees.

The acute TAS analysis used a NOEL of 0.05 mg/kg body weight for cholinesterase (ChE) inhibition from a human study (personal communication, Whang Phang). This is the same NOEL on which the reference dose for chronic exposure is based.

2. Residue Information: Food uses evaluated were published tolerances from 40 CFR 180.173 and food additive tolerances from 40 CFR 185.2750. Anticipated residue (AR) estimates for chronic exposure analyses were developed from FDA monitoring data and field residue data for the livestock feed items corn and sorghum, processing studies, and livestock feeding studies provided by the registrant. Anticipated residue data could not be developed for tea, so the tolerance was used for this commodity. A summary of

Ethion Dietary Exposure Analysis, page 2

the anticipated residue values used in the analysis is attached as Table 1a.

Anticipated residues used in the acute exposure analysis were maximum values from field residue studies, proposed tolerances, or tolerances (D. F. Edwards memo, 7/31/89). The residue values used in the acute exposure analysis are shown in Table 1b.

Anticipated residues for processed commodities (e.g., juice), were derived by multiplying the value for the raw agricultural commodity by the appropriate concentration/reduction factor determined from processing studies submitted by the registrant. This procedure was followed for residues used in both the chronic and acute exposure analyses. The methods used in deriving the AR data are fully described in two memoranda, D. F. Edwards to J. R. Tomerlin (7/31/89) and C. Deyrup to A. B. Kocalski (7/31/89).

3. Chronic Exposure Analysis: The TAS chronic exposure analysis uses tolerance level residues and 100 per cent crop treated to estimate the Theoretical Maximum Residue Contribution (TMRC) for the overall U.S. population and 22 population subgroups. An exposure estimate more closely approximating actual exposure, the Anticipated Residue Contribution (ARC), may be calculated using anticipated residue data. The TMRC and ARC exposure summaries for the overall U.S. population and all 22 TAS population groups are shown in Table 2. The TMRC and ARC exposure summaries for the overall U.S. population, non-nursing infants, and children aged 1 to 6 are compared in the following table.

Ethion TMRC-ARC Exposure Summary

	<u>Overall U.S. Population</u>	<u>Non-Nurs. Infants</u>	<u>Children Aged 1 - 6</u>
TMRC	0.016696 ^a 3339.3 ^b	0.042388 8477.7	0.038054 7610.7

^aEstimated exposure in mg/kg body weight/day.

^bExposure estimate expressed as a per cent of the PADI.

Ethion is registered for use on a relatively large number of crop commodities. The following table displays the exposure (ARC) summaries for selected commodity groups for the overall U.S. population, infants and children are shown in the following table.

4. Acute Exposure Analysis: The TAS acute exposure analysis estimates the distribution of single-day exposure for the overall U.S. population and certain population subgroups. The analysis evaluates individual food consumption, as reported by respondents in the 1977-78 USDA Nationwide Food Consumption Survey (NFCs), and accumulates exposure to ethion for each food consumed for which an ethion residue value exists. Each analysis assumes that ethion residues are present at the anticipated residue levels described shown in Table 1b in the entire supply of that food commodity.

The exposure distribution is compared to the NOEL observed in the acute toxicity study. Margins of Safety (MOS) for the average consumer are calculated according to the following relationship (shown for the overall U.S. population):

$$\begin{aligned}
 \text{Average MOS} &= \text{NOEL} / \text{Exposure (ARC)} \\
 &= 0.05 \text{ mg/kg} / 0.008219 \text{ mg/kg} \\
 &= 6
 \end{aligned}$$

As shown in the exposure distributions calculated from all commodities on which ethion may be used (Table 3), 45 per cent of the general population is expected to have an MOS less than 10 for ChE inhibition. The subgroup distributions show that 61 per cent of infants, 63 per cent of children aged 1 to 6, 40 per cent of adult females, and 41 per cent of adult males are estimated to have Margins of Safety for ChE inhibition less than 10. Ninety four per cent of infants are expected to consume at least 1 food on which ethion is registered; essentially every member of the overall population, children aged 1 to 6, adult females, and adult males are expected to consume at least one commodity which may have

ethion residues. The minimum MOS is less than 1 for each TAS population group.

Several assumptions regarding the TAS acute exposure analysis affect its interpretation. First, all foods on which ethion residues may exist that were consumed by a participant in the NFCS are assumed to be eaten at one meal. The food commodities that may contain ethion residues are relatively diverse: apples, dry beans, eggs, and melons, to name a few. If an individual consumed eggs and apple juice at breakfast, cantaloupe at lunch, and pinto beans at supper, his or her exposure would in reality occur over an extended period throughout the day. However, TAS assumes that the entire exposure occurs at one sitting.

Secondly, TAS assumes that the entire supply of commodities that may be treated with ethion do in fact contain ethion residues at the maximum levels observed in field studies. Although the available data are sparse, it is clear that residues lower than the maximum amount would occur in some samples of the commodity. This assumption, combined with the method TAS uses to accumulate daily exposure, leads to an overestimate of acute exposure.

In an attempt to provide more intelligible information regarding acute exposure to ethion, separate TAS acute analyses were conducted for specific food commodities and commodity groups. The results of these acute exposure analyses are shown in Table 4. The table shows the percentage of the population expected to consume at least one food which may contain ethion residues ("% Consumers"), the Margin of Safety for the average consumer of the commodities ("Avg. MOS"), the percentage of the population expected to have an MOS less than 10 ("% Cons. < 10"), and the minimum Margin of Safety expected for the population ("Min. MOS"). The residue data shown in Table 1b were assumed to be present in the entire commodity supply. For example, Table 4 gives a summary of exposure from grapes. Twenty seven per cent of the general population, 5 per cent of the infants, 35 per cent of the children aged 1 to 6, 24 per cent of the adult women, and 27 per cent of the adult men are expected to consume grapes or grape products each day. For those individuals who consume grapes or grape products, all the grapes, grape juice, wine, jam, jelly etc. is assumed to contain 3.3 ppm of ethion and all the raisins are assumed to contain 7.3 ppm of ethion.

Table 4 shows that acute exposure may result from consumption of a few specific products. The average Margin of Safety is in the hundreds to tens of thousands for grapefruit; apricots, cherries, and nectarines; eggs; grains; meats; nuts; and poultry. Moreover, no member of any of the TAS population groups is expected to have a MOS less than 10 because of ethion residues on any of these groups. By contrast, the minimum MOS for all five TAS population groups is less than 10 for apples and pears; grapes; melons; tomatoes; dry

Ethion Dietary Exposure Analysis, page 6

beans; succulent beans; strawberries and citrus fruits other than oranges and grapefruit; and plums and prunes. In many instances, the average MOS for ChE inhibition is less than 10 for some of these commodities. Table 4 also reveals a middle group of exposure comprised of peaches; miscellaneous vegetables (cucumbers, squash, eggplant, peppers, bulb vegetables, and sweet corn); tea; and oranges for which the average MOS is generally greater than 10, but one or more population groups have a segment of the population estimated to have a MOS for ChE inhibition less than 10.

Because the data presented in Table 4 is the summary from a series of exposure distributions, it is not possible to simply add the Margins of Safety or the percentages of the population with an MOS less than 10 shown for each commodity group to calculate the Margins of Safety for the general population.

5. Comments: The use of anticipated residue data significantly reduced the exposure estimates for all TAS population groups as compared to the estimates obtained using tolerance value residues. Although exposure to ethion in the overall U.S. population and several TAS population groups is greater than the reference dose, a substantial proportion of the exposure may be traced back to the tolerance residue for tea. Residue data for brewing studies using tea leaves containing ethion residues would likely result in lowered exposure estimates for tea and would probably result in overall exposure estimates less than the reference dose for most subgroups.

In addition to the fact that the bulk of the exposure comes from tea, for which only tolerance data are available, the reference dose for ethion has an additional 10 fold factor incorporated into the uncertainty factor used to calculate the reference dose. The receipt and review of additional toxicology data may result in the deletion of the additional 10 fold factor. If such were the case, the portion of the reference dose represented by the exposure would also change.

The interpretation of the acute exposure analyses is more subtle than that of the chronic exposure analysis. As discussed previously, the TAS acute exposure analysis uses individual food consumption data to estimate individual daily exposure. This daily exposure is calculated from all the foods consumed by an individual for which ethion has a registered use. Pesticide residues do not occur uniformly in the commodity supply, but rather are distributed. However, because the data currently available to EPA does not permit a detailed understanding of the distribution of ethion residues in the various commodities.

As pointed out previously, there are eight commodity groups for which every TAS population group has a segment with a MOS for ChE inhibition less than 10. Of these, apples and pears; melons

Ethion Dietary Exposure Analysis, page 7

(watermelon); tomatoes (except for juice); beans (dry and succulent); and strawberries (pooled with citrus other than orange and grapefruit) use tolerances or proposed tolerances to estimate the residue to be used in the acute exposure analysis. The possible implications of doing so are exemplified by melons (Table 4). On any given day, only 3 per cent of the population is expected to eat melon. However, of those who eat melons, 53 per cent are expected to have a MOS for ChE less than 10. The average MOS for melon consumers is only 6, and some members of the population will have a MOS for ChE less than 1. But, we do not have anticipated residue data for watermelons but used the tolerance of 2 ppm in the acute exposure analysis.

Dietary Exposure Branch recommended that the maximum values from field trial studies be used in the acute exposure analyses. Although this leads to an overestimate of acute exposure, the compositing of samples and the paucity of the data available from FDA monitoring programs (C. Deyrup to A. B. Kocialska memo, 7/31/89) dictate the use of this protective approach. Although compositing of samples is adequate for evaluating possible toxic effects resulting from an extended of exposure, such techniques are inappropriate for evaluating exposure to pesticides for a relatively short time frame.

In summary, the use of ethion apparently will not result in chronic health effects. This conclusion should be corroborated by a further analysis with residues in brewed tea. Moreover, there does not appear to be a health risk from short term exposure to ethion residues on grapefruit, stone fruits other than peaches and plums, eggs, grains, meat, nuts, or poultry. Short term exposure to ethion from residues on peaches, vegetables, tea, and oranges may result in ChE inhibition for selected TAS population, usually infants and children. Finally, inhibition of ChE may occur in all TAS population groups from short term exposure to ethion residues on apples and pears, melons, tomatoes, dry beans, succulent beans, strawberries and citrus other than oranges and grapefruit, and plums or prunes.
