- 7. <u>CONCLUSIONS</u>: This study is not scientifically sound. Survival in the solvent control was 62% which is considered unacceptable control survival by ASTM. The concentrations of several replicates were highly variable during the test. Based on reproductive data, mysids at all chlorothalonil concentrations tested were significantly affected. The NOEC and MATC could not be determined.
- 8. <u>RECOMMENDATIONS</u>: N/A.
- 9. BACKGROUND:
- 10. DISCUSSION OF INDIVIDUAL TESTS: N/A.

ř,

11. MATERIALS AND METHODS:

- A. <u>Test Animals</u>: Mysids (Mysidopsis bahia; ≤24 hours old) were obtained from in-house cultures maintained on a 16-hour light (30-100 ft-candles) photoperiod. The culture water was from the same source as the water used in the test. The temperature during culture was 25°C and the salinity of the culture water was approximately 32 parts per thousand (ppt). The mysids were fed brine shrimp nauplii.
- B. <u>Test System</u>: An intermittent-flow proportional diluter delivered test solution or control water to individual glass aquaria (39 x 20 x 25 cm). The aquaria were fitted with self starting siphons and the solution volume fluctuated between 4 and 7 l to ensure solution exchange. The volume of each aquarium was replaced an average of 13 times every 24 hours. The diluter was operated for approximately 30 days prior to test initiation.

The test aquaria were impartially positioned in a temperature-controlled water bath maintained at 25 ± 2 °C. Light was provided on a 16-hour light/8-hour dark photoperiod using fluorescent tubes with an intensity of 30-100 ft-candles.

Unpaired mysids were held in retention chambers constructed of glass petri dishes (10-cm in diameter) with 15-cm high nylon screen (363- μ m mesh) collars. Pairing chambers held sexually mature male and female pairs and were constructed of cylindrical glass jars (5.1 cm diameter, 10 cm high) containing two 1.9-cm holes covered with nylon screen.

A 0.44 mg a.i./ml stock solution was prepared by dissolving 0.1108 g of test material in acetone to volume in a 250-ml volumetric flask. An appropriate volume of the stock (43.5 μ l) was delivered to the diluter mixing chamber resulting in a high nominal exposure of 10 μ g/l which was diluted (50%) to provide the lower nominal concentrations.

The test dilution water was filtered (20 and 5 μ m) natural seawater collected from the Cape Cod Canal, Bourne, MA.

C. <u>Dosage</u>: Twenty-eight-day life-cycle toxicity test. Based on a preliminary testing, five nominal concentrations (0.63, 1.3, 2.5, 5.0, and 10 μ g a.i./l), a dilution water control, and a solvent control (23 μ l acetone/l) were used.

- CAR BARAN

. <u>5.3</u> -

D. <u>Design</u>: Mysids were impartially selected and distributed to 28 retention chambers until each contained 15 mysids. Two retention chambers were placed in each aquarium, yielding 30 mysids per replicate aquarium and 60 organisms per test level.

The mysids were fed 24 hour old brine shrimp nauplii twice daily.

To facilitate counting, the retention chambers were removed from the aquaria and placed on a black background. The number of live and dead mysids was determined daily and the chambers were gently brushed and siphoned to remove detritus. Any abnormal appearance or behavior was noted.

When the mysids reached sexual maturity (day 17), they were paired and transferred to isolation jars (10 per replicate). Mysids not used for reproduction were housed in a single retention chamber per replicate. Any paired males that died during the reproduction portion of the study were replaced. Dead females were not replaced. Reproductive output (number of offspring per female per reproductive day) was determined daily. "If the development of brood pouches used in distinguishing female organisms from males; was delayed due to toxicant exposure, those organisms were maintained in clean retention chambers until maturity was observed or until test termination."

At termination, the F_o mysids (males and females were recorded separately) were blotted dry, dried at 60°C for 24 hours, cooled in a desiccator, and weighed to the nearest 0.01 mg. Before drying, brine shrimp nauplii were removed from the female brood sacs when observed, but eggs and juveniles were not removed.

The dissolved oxygen concentration (DO) and pH were measured daily in each aquarium. The temperature and salinity in both replicates of the dilution water control were measured daily. Temperature of a solvent control chamber was continuously monitored using a minimum/maximum thermometer.

Water samples were collected from each replicate aquarium on days 0, 7, 14, 23, and 28 for chemical analysis. The highest test concentration was also

S EPA ARCHIVE DOCUMENT

MRID No. 424338-07

sampled on day 3 (but the results were not reported). The concentration of T-117-12 was determined using gas chromatography.

Ε. **Statistics:** The endpoints analyzed were survival, dry body weight by sex, and reproduction. The responses of the dilution water control and solvent control mysids were compared using t-tests. The survival, reproduction, and growth of the solvent and dilution water controls were not significantly different. A11 statistical comparisons of treatment response were made to the pooled control data. The survival data were arcsine square root transformed prior to analysis. Homogeneity of variance and normality for each data set were checked using Bartlett's test and the chi-square test, respectively. All data sets were analyzed using William's test and a 95% level of certainty.

12. <u>**REPORTED RESULTS:**</u> No undissolved test material was observed in the exposure solutions. The mean measured concentrations were 0.65, 0.83, 1.2, 3.0, and 5.7 μ g a.i./l (Table 2, attached).

The survival of adult mysids was reported in Table 3 (attached). After 28 days, there was no significant difference between pooled control and exposed mysid survival.

The number of offspring/female/reproductive day at concentrations $\geq 1.2 \ \mu g$ a.i./l was significantly reduced when compared to the pooled control (Table 3, attached).

Mean body weight at test termination (day 28) was not significantly affected by exposure to T-117-12 at the concentrations tested (Table 4, attached).

During the test, the DO was maintained between 79 and 117% of saturation. The pH was 7.7-8.0 and the temperature was 23-26°C. The salinity ranged from 31 to 33 ppt.

13. <u>STUDY AUTHOR'S CONCLUSIONS/QUALITY ASSURANCE MEASURES</u>: The maximum acceptable toxicant concentration (MATC) was <1.2 μ g a.i./l and >0.83 μ g a.i./l (geometric mean MATC = 1.0 μ g a.i./l), based on the most sensitive parameter, mysid reproduction.

Good Laboratory Practice statements were included in the report, indicating that the study was conducted in accordance with EPA Good Laboratory Practice Standards set forth in 40 CFR Part 160. The stability, characterization,

S EPA ARCHIVE DOCUMEN

MRID No. 424338-07

and verification of the test substance identity was the responsibility of the test sponsor. The dates of quality assurance inspections were included in the report.

my it .

14. REVIEWER'S DISCUSSION AND INTERPRETATION OF STUDY RESULTS:

A. <u>Test Procedure</u>: ASTM guidelines (1990) were used to evaluate this study. The test was not scientifically sound. Deviations from the ASTM were the following:

On test days 0, 7, and 23, several replicates had measured concentrations which were more than 30% higher than the time-weighted average concentrations (TWAC) for those replicates (Table 2, attached). Replicate A of the 2.5 μ g/l level (1.2 μ g/l mean measured concentration) was more than 30% higher than the TWAC on days 0 and 7 and less than 50% of the TWAC on day 23.

Survival in the solvent control replicate A was 47% (Table 3, attached). Survival in replicate B was 77% giving a combined survival for the solvent control of 62%. Control survival of at least 70% is required.

The test material was not identified by a batch or lot number.

Mysids were dried for only 24 hours; 72-96 hours or to a constant weight is recommended. In addition, the mysids were weighed to the nearest 0.01 mg; 0.001 mg is recommended.

The method used for transferring mysids to the test vessels was not described in the report or the study protocol. Mysids must be handled gently using nylon screen or wide-bore glass pipettes.

The temperature during the test $(23-26^{\circ}C)$ was lower than recommended $(27^{\circ}C)$.

No raw water quality values and survival, reproduction, or individual weight measurements were presented in the report.

B. <u>Statistical Analysis</u>: Survival data did not meet the assumption of homogeneity of variances due to zero variance in the dilution water control data. The data were analyzed using one-way analysis of variance (ANOVA) and Dunnett's and Kruskal-Wallis tests (Toxstat Version 3.3). Survival of the mysids was not

MRID No. 424338-07

significantly affected by exposure to the test material (see attached printout 1-3).

The reproduction data (except for the highest concentration where there was no reproduction) were analyzed using one-way ANOVA and various parametric multiple comparisons. Compared to the solvent control, there was no effect on reproduction (see attached printout 4). However, compared to the dilution water control, all exposed mysids had significantly reduced reproductive output. In this test, the solvent appears to adversely affect the mysids. Since the solvent concentration was not the same in all test concentrations (and the solvent control contained the highest solvent concentration used in the test), it would be best to compare the treatments to the dilution water control data.

Growth data were not analyzed since only the average growth by replicate data were included in the report.

C. <u>Discussion/Results</u>: This study is not scientifically sound. Survival in the solvent control was 62% which is considered unacceptable control survival by ASTM. The concentrations of several replicates were highly variable during the test. The NOEC and MATC could not be determined.

D. Adequacy of the Study:

- (1) Classification: Invalid.
- (2) Rationale: The test concentrations were variable and did not meet ASTM requirements. In addition, the average solvent control survival was only 62%.
- (3) Repairability: No.

15. <u>COMPLETION OF ONE-LINER FOR STUDY</u>: Yes, 09-30-92.

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY

WASHINGTON, D.C. 20460

OCT 8 1993

OFFICE OF PREVENTION, PESTICIDES AND TOXIC SUBSTANCES

MEMORANDUM

SUBJECT: Chlorothalonil: submission of individual growth data for mysid shrimp life-cycle study (MRID No. 424338-07).
FROM: Anthony Maciorowski, Branch Chief Hardward Ecological Effects Branch Environmental Fate and Effects Division (7507C)
TO: Walter Waldrop, PM 71 Reregistration Branch Special Review and Reregistration Division (7508W)

In EEB's review of July 22, 1993, the mysid shrimp life-cycle study (MRID No. 424338-07) conducted with chlorothalonil was upgraded from invalid to supplemental. The study had the potential to be upgraded to core upon submission of individual growth data for both male and female mysid shrimp. ISK Biotech Corporation has provided these data with the current submission.

Individual growth data were analyzed using one-way analysis of variance (ANOVA) and William's test (Toxstat Version 3.3). Results show that female body weight at test termination was not significantly affected by exposure to chlorothalonil technical at Male body weight, however, the concentrations tested. was significantly increased at the top two test concentrations (see attached) Therefore, the NOEL/LOEL for male mysid shrimp weight were found to be 1.2 ug/L and 3.0 ug/L, respectively. The reproductive NOEL/LOEL, however, were 0.83 ug/L and 1.2 ug/L, respectively (see DER).

This study may now be upgraded to core and will fulfill guideline requirements for the mysid shrimp life-cycle study 72-4(b) with technical chlorothalonil (T-117-12). If you have any questions, please contact Tracy Perry at 305-6451 or Henry Craven at 305-5320.
