Data Evaluation Report

1. Chemical: Chlorothalonil - 081901
2. Test Material: Technical Grade, Measured Concentrations
3. Study Type: Mollusk shell deposition study with eastern oyster

5. Review By: Daniel Rieder, Wildlife Biologist Hazard Evaluation Division
6. Approved By: Norman J. Cook, Head Section 2 Hazard Evaluation Division

7. Conclusions: The study is scientifically sound and fulfills guideline requirements for an estuarine mollusk acute shell deposition study under section 72.3. The results show an EC50 of 7.3 ppb with 95% C.L. of 4.9 - 12 ppb (nominal concentration). Based on measured concentrations the reviewer generated EC50 = 3.6 ppb with 95% C.L. of 2.9 to 4.3 ppb.

8. Recommendations: N/A

9. Background: This study was submitted to support registration.

10. Discussion of Individual Studies: N/A
11. **Materials and Methods:**

The measured test material was reported as chlorothalonil. The test animals were Eastern oysters (*Crassostrea virginica*) and were approximately 37-65mm long umbo to distal valve edge and weighed 1.1-4.9 grams (wet weight without shells, based on measurements of representative organisms). Mean height and weight were 53mm and 2.6g, respectively.

The test water was unfiltered natural seawater. Neither salinity nor temperature was altered.

The test was a 96-hour flow through exposure conducted in 9 liter glass aquaria containing 7 liters of test solution. Lighting was ambient window light supplemented with fluorescent lights during daylight hours. Salinity was 14-27 parts per thousand. The salinity dropped rapidly during the study due to heavy rains. Temperature was 14-16°C. Ten oysters were tested per test level. There were 6 test levels (1, 2, 4, 8, 16, and 32 ppb nominal), a control and solvent control (acetone). Water samples were collected daily from each treatment for residue analysis.

The EC50 was calculated using the moving average method. Shell growth of oysters in all treatments were compared to that of the solvent control by Students t-test to determine if the presence of chlorothalonil significantly affected new shell growth.

12. **Reported Results**

Concentrations of ≥ 4 ppb (nominal, 3.2 measured) significantly reduced new shell growth. The reported EC50 = 7.3 (95% C.L. = 4.9-12 ppb), nominal concentration.

* Using the deposition of the 2 ppb test level as 100%
During the test, DO remained at 100% saturation. After 96 hours, the pH in all test containers was 8.

13. **Study Author's Conclusions**

Based on the criterion of new shell growth, chlorothalonil caused significant reduction at 4 ppb and higher. The shell growth was significantly higher in oysters exposed to untreated seawater compared to the solvent control. However, the author's do not believe that there was any solvent effect because the two lowest test concentrations did not show a significant difference compared to the seawater control and they contained as much solvent as the solvent control.

14. **Reviewers Discussion**

A. **Test Procedure**

The test was conducted in an acceptable manner. One problem, relative to the SEP guidance, was reported. Salinity was reported as ranging from 27 ppt to 14 ppt, dropping rapidly during the test due to heavy rains. This, apparently, had no adverse effect on the seawater control organisms. The SEP states that source of test water should be an area were salinity fluctuates less than 6%. The reported salinity change in 4 days was substantially more than 6%.

B. **Statistical Analysis**

Independent Statistical analysis was performed generating an EC50

C. **Discussion of Results**

Since the solvent was not considered by the author as having a significant effect on shell deposition, the EC50 was recalculated using the seawater control as 100%. The resulting EC50 = 3.6 95% C.L. = 29 - 4.3 ppb). See attached printout of statistical calculation result. Interpreting results and determining a NOEL for a study with continuous (not discrete) values is difficult. Particularly when the
solvent may have had an adverse effect on shell deposition. It is reasonable to assume that the two lowest treatment levels had minimal, if any effects on the oysters over that caused by the solvent. However, it is also assumed that in the low ppb's chlorothalonil will significantly reduce shell deposition during a 96-hour exposure. The most conservative EC50 (3.6 ppb) will be used in risk assessments to evaluate impact to nontarget mollusks including endangered species.

Because the number of organisms used was so large, the 95 percent confidence intervals calculated from the binomial probability are unreliable. Use the intervals calculated by the other tests.

An approximate LC50 for this set of data is 2.906392

Results calculated using the moving average method:

<table>
<thead>
<tr>
<th>SPAN</th>
<th>G</th>
<th>LC50</th>
<th>95 PERCENT CONFIDENCE LIMITS</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>2.327294E-02</td>
<td>[3.569999, 2.937949, 4.278396]</td>
<td></td>
</tr>
</tbody>
</table>

Results calculated using the probit method:

<table>
<thead>
<tr>
<th>ITERATIONS</th>
<th>G</th>
<th>H</th>
<th>GOODNESS OF FIT PROBABILITY</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>.162968</td>
<td>3.930252</td>
<td>3.417194E-03</td>
</tr>
</tbody>
</table>

Since the probability is less than 0.05, results calculated using the probit method probably should not be used.

Slope = 1.57533

95 percent confidence limits = .9393801 and 2.21128

LC50 = 3.463157

95 percent confidence limits = 1.972898 and 5.657444

LC10 = .5411176

95 percent confidence limits = .1195157 and 1.106666
