### **CONCLUSIONS**

# Field Dissipation - Terrestrial

- 1. This study is scientifically valid and provides supplemental information on the terrestrial field dissipation of flumioxazin in lysimeter-enclosed soybean plots of loam soil in Indiana.
- 2. Uniformly phenyl ring-labeled [14C]flumioxazin, applied as a pre-emergent at a nominal application rate of 45 g a.i./A (0.361 mg/lysimeter) to lysimeter-enclosed soybean plots of loam soil in Charlestown, IN, dissipated with a registrant-calculated half-life of 4.8 days (0-16 day data;  $r^2 = 0.86$ ); the half-life was determined only from the parent compound detected in the 0- to 3-inch depth. Dissipation was observed to be biphasic with the more rapid phase occurring through 16 days. The observed first half-life occurred between 0 and 2 days posttreatment. Residue data were reported as means of two replicates; concentration data were reported as parent equivalents. The parent compound was initially present in the 0- to 3-inch depth at 88.5% (0.13 ppm) of the applied radioactivity, was 50.2% (0.060 ppm) at 2 days and 28.0-33.5% (0.032-0.045 ppm) from 5 to 9 days posttreatment, and was 0.9% (0.001 ppm) at 106 days. The minor degradates APF and 482-HA were detected at maximums of 8.2% (0.010 ppm, day 2) and 2.6% (0.004 ppm, day 0) of the applied radioactivity, respectively. The minor degradates 482-CA and IMOXA were present at  $\leq 1.9\%$  ( $\leq 0.002$  ppm, days 2 to 72) and  $\leq 1.3\%$  ( $\leq 0.001$  ppm, days 2 to 106) of the applied radioactivity, respectively. Total [14C] residues were not detected above 0.01  $\mu$ g/g (designated as the level of analysis) below the 3-inch depth. Nonextractable [14C]residues were initially 7.5% of the applied radioactivity, were 28.6% at 2 days posttreatment, increased to 51.7% by 5 days, and were a maximum of 93.1% at 316 days.

Total [\$^4\$C]residues detected in the leachate samples were 0.33% of the applied radioactivity throughout the study period. Characterization data for the leachate samples were reported only for samples containing \$\geq 0.001 \mu g/mL \total [\$^4\$C]residues. The parent compound was detected at 0.01-0.08% (0.03-0.48 ppb) at 5, 16, 37, and 44 days posttreatment. The minor degradates APF and 482-HA were detected at 0.0-0.19% (0.07-1.6 ppb) and 0.0-0.31% (0.09-12.3 ppb) from 5 to 72 days posttreatment, respectively. Total [\$^4\$C]residues detected in the run-off samples were 0.55% of the applied radioactivity throughout the study period. Characterization data for the run-off samples were reported only for samples containing \$\geq 0.001 \mu g/mL \total [\$^4\$C]residues. The parent compound was detected at \$\leq 0.01%\$ (\$\leq 0.76 \text{ ppb}\$) at 16, 37, and 44 days posttreatment. The minor degradate APF was detected at \$\leq 0.05%\$ (\$\leq 1.5 \text{ ppb}\$) from 16 to 58 days posttreatment.

### **METHODOLOGY**

Uniformly phenyl ring-labeled [14C]flumioxazin (formulation not reported; V-53482; radiochemical purity ≥99%, specific activity 348 µCi/mg; Figure 1, p. 57), dissolved in dimethyl sulfoxide, was applied once (as a pre-emergent) at a nominal rate of 45 g a.i./A (0.361 mg/lysimeter) to 8-inch diameter steel lysimeter-enclosed soybean plots of loam soil (0-3 inches: 47.6% sand, 35.1% silt, 17.3% clay, 2.2% organic carbon, pH 7.0, CEC 9.7 meq M+/100 g; Table I, p. 48) in Charlestown, IN (pp. 15, 16). Prior to treatment, the test plot was treated twice with Roundup<sup>®</sup> (glyphosate, formulation not reported; see Comment #15) to destroy vegetation, and 40 steel lysimeters (38-inch length; 8-inch i.d.) were inserted vertically into the soil to a target depth of 36 inches (leaving the rim two inches above the soil surface; p. 17). The lysimeters were inserted on both sides of an access trench (5 feet deep x 5 feet wide x 35 feet long; Appendix 11, Figure 1, p. 248). The lower end of the soil column was fitted with a wire mesh and the lysimeter was equipped with a leachate collection apparatus consisting of a glass funnel inserted into a glass collection jar (p. 17). An overflow collection apparatus, consisting of Teflon tubing inserted through a hole in the lysimeter (0.25 inches above the soil surface) and connected to a glass jar, was used to collect water that pooled on the top of the soil surface. The lysimeters remained untreated for 16 days prior to the initiation of the study; lysimeterenclosed plots received one inch of water (via irrigation) prior to treatment. Three soybean seeds (var. FFR 398) were planted (one-inch depth) in each lysimeter immediately prior to treatment (p. 18); following germination, the two smallest plants were cut at ground level and removed. The soil surfaces within 29 lysimeters were individually treated drop-wise around the inner six-inch area with the test solution using a glass Pasteur pipette (p. 20); each lysimeter was immediately irrigated with 100 mL of well water following treatment. Of the remaining lysimeters, three were utilized as controls and four were treated with KBr to monitor the wetting front associated with the pesticide treatment (p. 18). The test plot containing the lysimeters was not treated with pesticides for at least twelve years prior to treatment with flumioxazin (p. 16). The depth to the water table was not reported. Environmental data were collected on-site (p. 19) with the exception of pan evaporation data (Appendix 5, pp. 184-189). Precipitation was supplemented with irrigation; total water input (58.8 inches) during the study period was approximately 155% of the 12-year mean annual precipitation (Table III, pp. 50-51; Figure 5, p. 62). Through 97 days posttreatment, pan evaporation was 14.9 inches (reviewer-calculated) and total water input was 13.1 inches (Appendix 5, pp. 184-189; see Comment #2).

Duplicate treated lysimeters were removed at 0, 2, 5, 9, 16, 27, 48, 72, 106, and 316 days posttreatment; single control lysimeters were removed at 0, 72, and 316 days posttreatment; and KBr-treated lysimeters were removed at 106 days (one lysimeter) and 316 days posttreatment (three lysimeters; Table II, p. 49). Samples were collected by removing the entire lysimeter from the plot (p. 21). The top three inches of soil were transferred to sample bags, and the steel lysimeters (0-106 day samples) were cut open with a reciprocating saw. The soil columns within the lysimeters were sectioned into 3-inch (0- to 12-inch depth) and 6-inch (12- to 36-inch depth) increments, and shipped

frozen (on dry ice) to the PTRL East analytical lab; lysimeters removed at 316 days posttreatment were processed at the analytical lab. At the PTRL East analytical lab, the soil was homogenized and triplicate subsamples were analyzed for total radioactivity by LSC following combustion; the limit of quantitation (56 dpm/g) was twice background. Soil samples containing  $\geq 0.01~\mu g/g$  [ $^{14}$ C]residues were shipped to PTRL West, Inc., and extracted and analyzed (p. 24). Soil samples were stored frozen at PTRL West, Inc. for less than one week prior to analysis (Appendix 3, p. 98). Control lysimeters (days 72 and 316) were removed and used to quantify background radioactivity, and to determine gravimetric moisture in each soil layer (p. 22). Leachate and run-off water samples were monitored approximately once per week (p. 23). When leachate/run-off was present in the collection jars, samples were placed into collection vials and stored frozen, or immediately shipped frozen to the PTRL East analytical lab.

At PTRL West, Inc., soil samples were analyzed for the parent and the following potential degradates: N-[7-fluoro-3-oxo-4-(2-propynyl)-2H-1,4-benzoxazin-6-yl]-3,4,5,6tetrahydrophthalamic acid (482-HA); 2-[7-fluoro-3-oxo-6-(3,4,5,6tetrahydrophthalimido)-2H-1,4-benzoxazin-4-yl]propionic acid (482-CA); 7-fluoro-6-(3,4,5,6-tetrahydrophthalimido)-2H-1,4-benzoxazin-3(4H)-one (IMOXA); 6-amino-7fluoro-4-(2-propynyl)-2H-1,4-benzoxazin-3(4H)-one (APF); 7-fluoro-6-nitro-4-(2propynyl)-2H-1,4-benzoxazin-3(4H)-one (PNF); SAT-482; and 482PHO (Appendix 3, Figure B1, p. 119). Soil samples were extracted three times by sonicating and shaking with acetone: 0.1 N HCl (4:1, v:v) and centrifuged, and the supernatants were decanted (Appendix 3, p. 98; Figure B3, p. 123). The extracts were combined and triplicate aliquots were analyzed for total radioactivity by LSC; the limit of detection was 35 dpm above background. Aliquots of the extracts were concentrated under nitrogen or by rotary evaporation, and redissolved in methanol:water (2:3, v:v). The redissolved extracts were centrifuged (to remove particulates), and triplicate aliquots of the supernatant were analyzed for total radioactivity by LSC. Aliquots of the supernatant were also analyzed by reverse-phase HPLC (Supelcosil LC-DP column) using a mobile phase gradient of water:methanol (both with 0.05% H<sub>2</sub>PO<sub>4</sub>; 60:40 to 0:100, v:v) with UV (254 nm) and radioactive flow detection (Appendix 3, pp. 95, 96). Samples were co-chromatographed with nonradiolabeled reference standards; the limit of quantitation was not reported. Eluent fractions were collected at one-minute intervals and analyzed for total radioactivity by LSC. To confirm compound identities, selected extracts (2, 9, 27, 48, and 72 days) were concentrated, redissolved in acetonitrile or methanol, and analyzed by twodimensional TLC using silica gel plates developed in the first dimension with benzene:ethyl acetate (4:1, v:v), and in the second dimension with ethyl acetate: ethanol (4:1, v:v; days 9, 27, and 48), ethyl acetate:ethanol:glacial acetic acid (80:20:0.4, v:v:v; day 72), or 100% ethyl acetate (day 2; Appendix 3, pp. 97, 99; Figure B6, pp. 132-141). Areas of radioactivity were detected by radioimage scanning. Samples were co-chromatographed with nonradiolabeled reference standards which were visualized with UV (254 nm) light and/or iodine staining. Post-extracted soil samples were analyzed for total radioactivity by LSC following combustion.

Triplicate aliquots of the leachate and run-off samples were analyzed for total radioactivity by LSC at the PTRL East analytical lab; the limit of quantitation (70 dpm/mL) was twice the background (p. 25). Samples containing  $\geq 0.001~\mu g/mL$  [ $^{14}$ C]residues were shipped to PTRL West, Inc., for characterization of [ $^{14}$ C]residues. At PTRL West, Inc., samples were centrifuged (to remove particulates) and triplicate aliquots of the supernatant were analyzed for total radioactivity by LSC (Appendix 3, p. 99). Samples were analyzed by HPLC as previously described for the soil samples. Selected samples (day 16) were concentrated by a nitrogen stream or rotary evaporation, dissolved in acetonitrile or methanol, and analyzed by two-dimensional TLC developed in the first dimension with benzene:ethyl acetate (4:1, v:v), and in the second dimension with ethyl acetate:ethanol (4:1, v:v) or ethyl acetate:ethanol:acetic acid (80:20:0.4, v:v; Appendix 3, Figures B8, B11; pp. 148-151, 165-166).

In a method validation study, duplicate soil samples were fortified with flumioxazin (fortification not specified) and extracted (method not specified); the extracts were combusted, dried, redissolved in methanol:water (2:3, v:v), and analyzed by HPLC as previously described (Appendix 3, p. 102). Recovery of the parent was 91.3% of the applied radioactivity (Appendix 3, Table B1, p. 108).

### **DATA SUMMARY**

Uniformly phenyl ring-labeled [14C]flumioxazin (V-53482; radiochemical purity ≥99%), applied as a pre-emergent at a nominal application rate of 45 g a.i./A (0.361 mg/lysimeter) to lysimeter-enclosed soybean plots of loam soil in Charlestown, IN, dissipated with a registrant-calculated half-life of 4.8 days (0-16 day data;  $r^2 = 0.86$ ; Appendix 3, Figure B13, p. 169); the half-life was determined only from the parent compound detected in the 0- to 3-inch depth (see Comment #7). Dissipation was observed to be biphasic with the more rapid phase occurring through 16 days. The observed first half-life occurred between 0 and 2 days posttreatment. Residue data were reported as means of two replicates; concentration data were reported as parent equivalents. The parent compound was initially present in the 0- to 3-inch depth at 88.5% (0.13 ppm) of the applied radioactivity, was 50.2% (0.060 ppm) at 2 days and 28.0-33.5% (0.032-0.045 ppm) of the applied from 5 to 9 days posttreatment, decreased to 6.0-13.2% (0.007-0.015 ppm) by 16-48 days posttreatment, and was 0.9% (0.001 ppm) of the applied at 106 days posttreatment (Appendix 3, Tables BV, BVI, pp. 113, 114). The minor degradate 6amino-7-fluoro-4-(2-propynyl)-2H-1,4-benzoxazin-3(4H)-one (APF) was initially present (day 0) at 5.4% (0.008 ppm) of the applied radioactivity, was a maximum of 8.2% (0.010 ppm) of the applied at 2 days posttreatment, and was last detected at 2.3% (0.003 ppm) at 9 days posttreatment. The minor degradate N-[7-fluoro-3-oxo-4-(2-propynyl)-2H-1,4benzoxazin-6-yl]-3,4,5,6-tetrahydrophthalamic acid (482-HA) was detected once, at 2.6% (0.004 ppm) of the applied at day 0. The minor degradate 2-[7-fluoro-3-oxo-6-(3,4,5,6tetrahydrophthalimido)-2H-1,4-benzoxazin-4-yl]propionic acid (482-CA) was present at

 $\leq 1.9\% (\leq 0.002 \text{ ppm})$  of the applied radioactivity from 2 to 72 days posttreatment. The minor degradate 7-fluoro-6-(3,4,5,6-tetrahydrophthalimido)-2H-1,4-benzoxazin-3(4H)one (IMOXA) was present at  $\leq 1.3\%$  ( $\leq 0.001$  ppm) of the applied radioactivity from 2 to 106 days posttreatment. An unidentified minor degradate (designated as "D3") was initially present (day 2) at 5.3% (0.006 ppm) of the applied radioactivity, was 3.1% (0.004 ppm) of the applied at 5 days posttreatment, was a maximum of 5.5% (0.007 ppm) of the applied at 9 days posttreatment, and was last detected at 0.8% (0.001 ppm) at 48 days posttreatment. Unidentified radioactivity (designated as "All Others") was present at 1.5-6.3% (0.002-0.007 ppm) of the applied radioactivity from 0 to 106 days posttreatment; unidentified radioactivity consisted of multiple components, each of which was ≤0.002 ppm. Total [ $^{14}$ C]residues were not detected above 0.01  $\mu$ g/g (designated as the level of analysis) below the 3-inch depth (Table V, p. 54). Nonextractable [14C]residues were initially 7.5% of the applied radioactivity, were 28.6% of the applied at 2 days posttreatment, increased to 51.7% of the applied by 5 days posttreatment, and were a maximum of 93.1% of the applied at 316 days posttreatment (Table BIV, pp. 111, 112; see Comment #1).

Total [ $^{14}$ C]residues detected in the leachate samples were 0.33% of the applied radioactivity throughout the study period (Table VI, p. 55). Characterization data for the leachate samples were reported only for samples containing  $\geq 0.001~\mu g/mL$  total [ $^{14}$ C]residues (5, 16, 37, 44, and 72 days). The parent compound was detected at 0.01-0.08% (0.03-0.48 ppb) of the applied at 5, 16, 37, and 44 days posttreatment (Appendix 3, Table BVIII, p. 116). The minor degradates APF and 482-HA were detected at 0.0-0.19% (0.07-1.6 ppb) and 0.0-0.31% (0.09-12.3 ppb) of the applied from 5 to 72 days posttreatment, respectively. Three unidentified minor degradates (designated as "D1, D3, and D4") were detected at  $\leq 0.32\%$  ( $\leq 2.7$  ppb) of the applied radioactivity. Unidentified radioactivity (designated as "All Others") was detected at 0.0-0.85% (0.37-5.3 ppb) of the applied radioactivity from 5 to 72 days posttreatment; unidentified radioactivity consisted of multiple components, each of which was  $\leq 1.6$  ppb.

Total [ $^{14}$ C]residues detected in the run-off samples were 0.55% of the applied radioactivity throughout the study period (Table VI, p. 55). Characterization data for the run-off samples were reported only for samples containing  $\geq 0.001~\mu g/mL$  total [ $^{14}$ C]residues (16, 37, 44, and 58 days). The parent compound was detected at  $\leq 0.01\%$  ( $\leq 0.76~ppb$ ) at 16, 37, and 44 days posttreatment (Appendix 3, Table BX, p. 118). The minor degradate APF was detected at  $\leq 0.05\%$  ( $\leq 1.5~ppb$ ) from 16 to 58 days posttreatment. Three unidentified minor degradates (designated as "D1, D2, D3, and D4") were detected at  $\leq 0.33\%$  ( $\leq 9.6~ppb$ ) of the applied radioactivity from 16 to 58 days posttreatment. Unidentified radioactivity (designated as "All Others") was detected at 0.18% (0.42-3.8 ppb) from 16 to 58 days posttreatment; unidentified radioactivity consisted of multiple components, each of which was  $\leq 1.6~ppb$ .

Material balances (based on LSC analysis) were 96.4-106.1% of the applied radioactivity from 0 to 9 days posttreatment, were 64.9% of the applied at 16 days posttreatment, and were 72.9-81.1% of the applied from 27 to 316 days posttreatment with the exception of 56.4% at 106 days (Table V, p. 54; see Comment #10; also see Table BIII, p. 110).

# **COMMENTS**

- 1. Nonextractable [14C]residues were considerably high following 2 days posttreatment (Table BIV, pp. 111-112). Nonextractable [14C]residues were 28.6% of the applied radioactivity at 2 days posttreatment, were 51.7% of the applied at 5 days posttreatment, and generally increased to a maximum of 93.1% of the applied by 316 days posttreatment (also see Comment #10). The study author stated that soil samples were extracted three times by sonicating and shaking with acetone:0.1 N HCl (4:1, v:v; p. 98). The reviewer noted that the observed first half-life occurred between 0 and 2 days before the nonextractable residues became unreasonably high. Additionally, the reviewer noted that the all residues detected in the soil (above the limit of analysis) remained in the top layer of the soil (0-3 inches). However, water balance data were inconclusive and it could not be confirmed that conditions were favorable for leaching (also see Comment #2).
- 2. Pan evaporation data were incomplete; data were only reported through 97 days posttreatment. Through 16 days posttreatment, pan evaporation was 3.4 inches and total water input was 3.9 inches (Appendix 5, p. 184), which may have created somewhat favorable conditions for leaching. However, the study authors reported that 2.52 inches of rain fell on the site from 9 to 16 days posttreatment as a result of Hurricane Erin; it is unclear whether preferential flow occurred following the rain (also see Comment #5). Additionally, the reviewer notes that 303 mL of run-off water was collected and removed from the lysimeters through 16 days posttreatment, which might have created a negative water balance by decreasing the actual water input value (Table IV, p. 52). Also, the study authors reported that the recovery of the bromide tracers in the leachate samples were highly variable (see Comment #6). The reviewer notes that the registrant-calculated half-life of the parent was 4.8 days, and that >90% of the parent detected in the 0- to 3inch soil depth had dissipated by 16 days posttreatment. Based on reported water balance data, however, the reviewer was unable to confirm that conditions were favorable for leaching.
- 3. The study was not conducted under typical use conditions. The lysimeters (8-inch inner diameter) were too small to be representative of actual use conditions, the method of application was atypical (glass Pasteur pipette), and only limited areas of the plot (the inner six inches of the lysimeter) were treated (p. 20).
- 4. Storage stability data were not reported. The study authors stated that the degradate 482-HA was stable in a leachate sample which was re-analyzed after 26 days of frozen storage

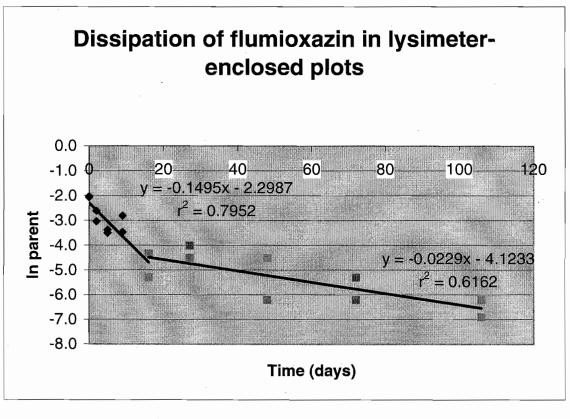

- (p. 101). If leachate samples were stored for >30 days, a valid stability study must be included to demonstrate stability of the parent and degradates in the leachate. The study authors reported that soil samples were extracted and analyzed within one week of arrival at the analytical lab (p. 98).
- 5. The study authors reported that the most significant leaching occurred at the day 16 sampling interval (pp. 37, 38, Table VI, p. 55). The study authors stated that the radioactivity found in the leachate could have been caused by "preferential flow" occurring in the lysimeters, or by "edge effects" transporting the test substance down the edge of the soil column due to heavy rainfall. The study authors reported that 2.52 inches of rain fell on the site from 9 to 16 days posttreatment as a result of Hurricane Erin (p. 38).
- 6. The study authors stated that the recovery of the bromide tracer in leachate samples from the lysimeters treated with KBr was highly variable (p. 12). Cumulative recoveries of bromide in leachate samples were 0.7%, 10.8%, and 14.6% of the applied radioactivity from lysimeters treated with KBr and sampled at 246, 285, and 285 days posttreatment, respectively (p. 40; Figure 7, p. 64; Appendix 9, pp. 226, 227); recoveries in run-off samples were ≤0.8% of the applied radioactivity. The study authors stated that recovery of bromide in leachate samples from the lysimeter sampled through 240 days posttreatment indicated that the lysimeter "was relatively poorly drained and not representative of the general leaching potential at the site" (p. 40).
- 7. The registrant-calculated half-life was based on data from the 0- to 3-inch depth, rather than the 0- to 6-inch depth. However, the study authors reported that [14C]residues detected below the 0- to 3-inch depth were not detected above the "limit of analysis" (<0.01 ppm; p. 36).
- 8. The residue data for the parent and degradates were reported as units of concentration and as percentages of the nominal ("dose") radioactivity (Appendix 3, Table BV, p. 113); the reviewer noted, however, that the dose rate (mg parent/g soil) varied between soil columns because the same amount of parent was applied to each column, but each column weighed a different amount thereby resulting in different initial concentrations (Appendix 8, pp. 209-225).
- 9. The limits of detection and quantitation were not reported for HPLC or TLC analyses. Both limits of detection and quantitation should be reported to allow the reviewer to evaluate the adequacy of the method of the determination of the test compound and its degradates.
- 10. Material balances are generally not required for terrestrial field dissipation studies and are generally not reported since nonradiolabeled compounds are usually used. Because this study was conducted with radiolabeled test compounds applied in lysimeters, material balances were reported. A general pattern of decline over time was observed in the

material balances which were 72.9-106.1% of the applied radioactivity from 0 to 316 days posttreatment (Table V, p. 54); however, data were variable over time. The study authors stated that the decrease in the material balances over time was likely due to "codistillation" during a three-day drying period following the first heavy rainfall at the day-16 sampling interval (p. 39). However, the reviewer questions how the values in Table V were determined since data in Table BIV (p. 111) indicate that nonextractable residues were present at a higher percentage of the applied than would be theoretically possible based on the reported material balances. Based on data in Table BIII (p. 110), material balances were higher than those reported in Table V. The reviewer notes that the terms "% of dose" and "percent accountability" should be clearly defined in terms of the nominal or actual application rate and that it is preferable that the same terms be used consistently throughout the study. Clarification by the registrant is necessary.

- 11. The study authors stated that, following treatment, the vials used to deliver the test material were analyzed for total radioactivity by LSC to confirm the transfer of the test material to the soil columns (p. 34). Mean radioactivity remaining in the vials was 0.14% of the applied radioactivity.
- 12. The study was conducted at one site (Indiana). Additional terrestrial field dissipation studies conducted in North Carolina (MRID 44295043), Illinois (MRID 44295044), Mississippi (MRID 44295045), and Iowa (MRID 44295046) were also submitted.
- 13. The study author reported that the soil at the test site was a Wheeling silt loam soil (pp. 13, 16); however, the study authors stated that "the soil texture was classified as a loam for the entire lysimeter" (p. 32). Based on soil characterization data reported, the reviewer reported the soil as a loam soil.
- 14. The proposed degradation pathway for flumioxazin is presented in Figure B12 (Appendix 3, p. 167).
- 15. The study authors stated that cicada-killer wasps (*Sphecius speciosus spp.*) were found nesting in the soil around the lysimeters (August 1995, p. 33). The study authors stated that the eggs were deposited at a shallow depth and did not cause significant damage to the soil profile. Additionally, ants were observed in the lysimeters (August 1995). To control the insect infestation, the soybeans and soil surfaces were treated with malathion (formulation not reported) and diazinon (5% granules) on August 11, 1995 (16 days posttreatment).
- 16. The study authors reported that the formulation of flumioxazin was prepared with 0.5 mL of a formulation blank (containing 500 mL HPLC-grade water, Morwet D-425, Morwet EFW, and ASP-400P) plus 10 mL of HPLC-grade water in a vial containing [14C]flumioxazin dissolved in dimethyl sulfoxide (p. 20). The reviewer assumes the

- formulation is in the form of a wettable powder; however, the exact formulation was not specified. Clarification by the registrant is necessary.
- 17. The parent was applied at an exaggerated rate (45 g a.i./A); the reviewer noted in an additional lysimeter study the proposed maximum use rate for flumioxazin is 36.1 g a.i./A for soybeans and 43.4 g a.i./A for peanuts (MRID 44295043, p. 10).

1. 1						

<sup>&</sup>lt;sup>a</sup> TLC solvent system A was Benzene: Ethyl Acetate (4:1, v:v)

b TLC solvent system B was Ethyl Acetate:Ethanol (4:1, v:v)

<sup>&</sup>lt;sup>c</sup> TLC solvent system C was Ethyl Acetate:Ethanol:Glacial Acetic Acid (80:20:0.4, v:v:v)

TLC solvent system D was Ethyl Ether (100%)

Note, two-dimensional TLC employed solvent system A in the first dimension followed by either B, C, or D in the second dimension.

HPLC retention time values were subject to variation between runs. The size of injection loop used (1 mL for soil extracts and 5 mL for leachate and runoff) had a direct and predictable effect on the observed retention time. Standards were always co-injected with samples and clear separation of standards was achieved.

[phenyl-14C]Flumioxazin

7-Fluoro-6-(3,4,5,6-tetrahydrophthalimido)-

4-(2-propynyl)-1,4-benzoxazin-3(2H)-one

CAS No.: 103361-09-7

Supplier: Sumitomo Chemical Company

Lot No.: R1S93013

Specific Activity: 123 mCi/mmol (348 µCi/mg)

Radiochemical Purity: 99.4% as determined by PTRL West, Inc.

Figure B12. Proposed Metabolic Pathway.

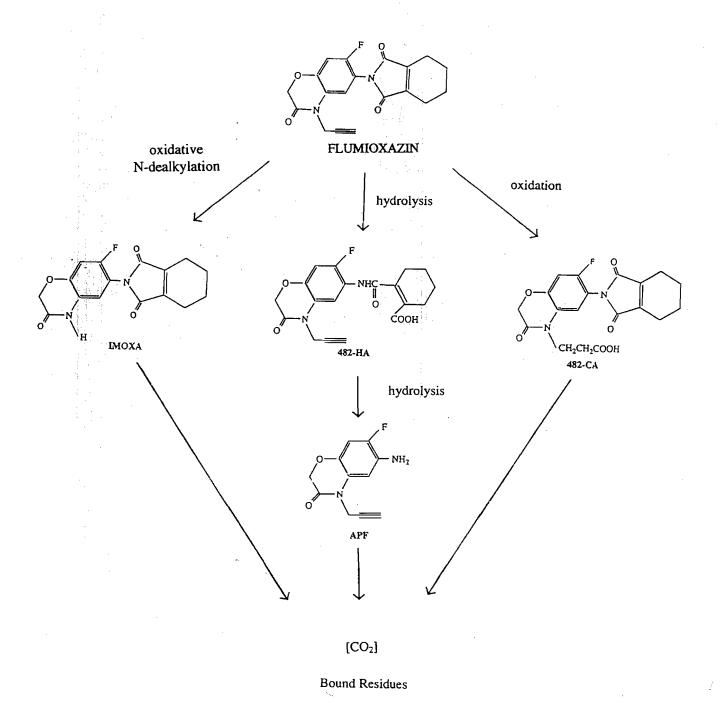

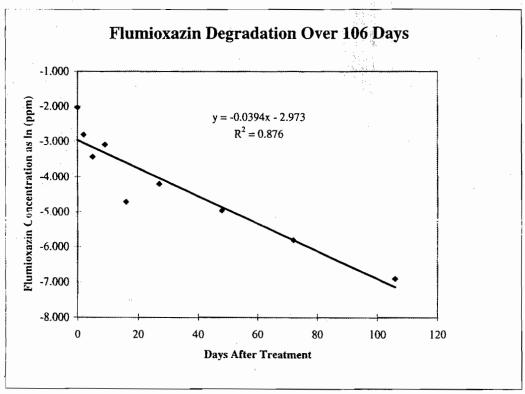

Figure B13. Flumioxazin Degradation Kinetics.

Days After Treatment	Flumioxazine Residues in Soil (ppm)	Natural Log of Flumioxazine Residues in Soil (ppm)
0	0.130	-2.040
2	0.060	-2.813
5	0.032	-3.442
9	0.045	-3.101
16	0.009	-4.711
27	0.015	-4.200
48	0.007	-4.962
72	0.003	-5.809
106	0.001	-6.908

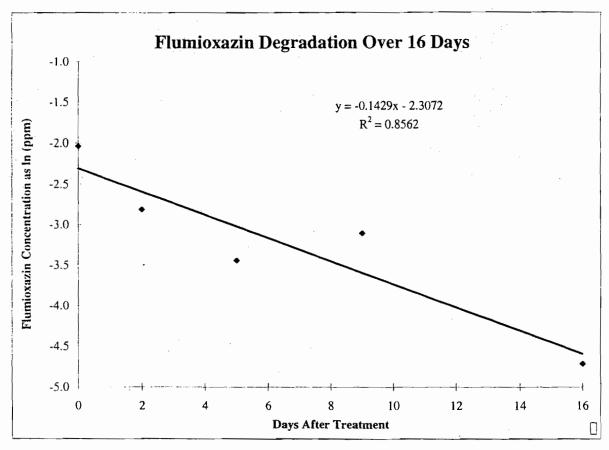

Calculated Half-Life = 0.693/0.0394 = 17.6 Days

Note, the y-intercept correponds to only  $\sim 0.05$  ppm and the actual Time 0 concentration was 0.13 ppm.

This Regression Analysis Was Not Used To Obtain The Definitive Half-Life

Figure B13 (cont.). Flumioxazin Degradation Kinetics.

DAT	Flumioxazine Residues in Soil (ppm)	Natural Log of Flumioxazine Residues in Soil (ppm)
0	0.130	-2.040
2	0.060	-2.813
5	0.032	-3.442
9	0.045	-3.101
<b>16</b>	0.009	-4.711

Half-Life = 0.693/0.1429 = 4.8 Days

<sup>[</sup>a] Data obtained from NOAA stations located at Dubois South Indiana Forage Farm, and Nolin River Lake, Kentucky.

<sup>[</sup>b] Datum is not available.

<sup>[</sup>c] Cumulative rainfall reaching lysimeters was not calculated until 0 DAT.

<sup>[</sup>d] Lysimeters were covered during severe weather, therefore daily rainfall reaching lysimeters was less than the actual rainfall (2.27 inches) recorded at the test site.

<sup>[</sup>a] Data obtained from NOAA stations located at Dubois South Indiana Forage Farm, and Nolin River Lake, Kentucky.

<sup>[</sup>b] Datum is not available.

<sup>[</sup>c] Lysimeters were covered during severe weather, therefore daily rainfall reaching lysimeters was less than the actual rainfall (2.17 inches) recorded at the test site.

<sup>[</sup>a] Values presented are corrected for a background radioactivity of 28 dpm/g moist soil. Therefore, reported values greater than or equal to 28 dpm are above the Limit of Quantitation (LOQ), which is 28 dpm/g moist soil.

<sup>[</sup>b] Level of Analysis (LOA) is 0.01  $\mu$ g/g or 7726 dpm/g dry soil.
