# Predicted occurrence of coldwater fish assemblages in New Hampshire wadeable streams

By  
David Neils

## Purpose

- DES maintains separate dissolved oxygen criteria for “coldwater” streams from Oct. 1 – May 14 (to June 30 for late spawners)
- Strict coldwater fish assemblages are geographically defined; but doesn't include all streams where more diverse coldwater fish assemblages occur
- Assists in defining where warmwater communities are expected
- Useful for establishing instream water temperature criteria

A photograph of a forest stream with a white box containing text. The stream flows through a dense forest with many trees and green foliage. The water is clear and flows over rocks. The white box is positioned in the center of the image, containing three bullet points.

## Objectives

- To determine if a model could be built that predicts where cold water fish communities are expected occur
- Decide what variables are important in determining the presence or absence of cold water fish communities
- Assess the practicality of applying the model's results statewide

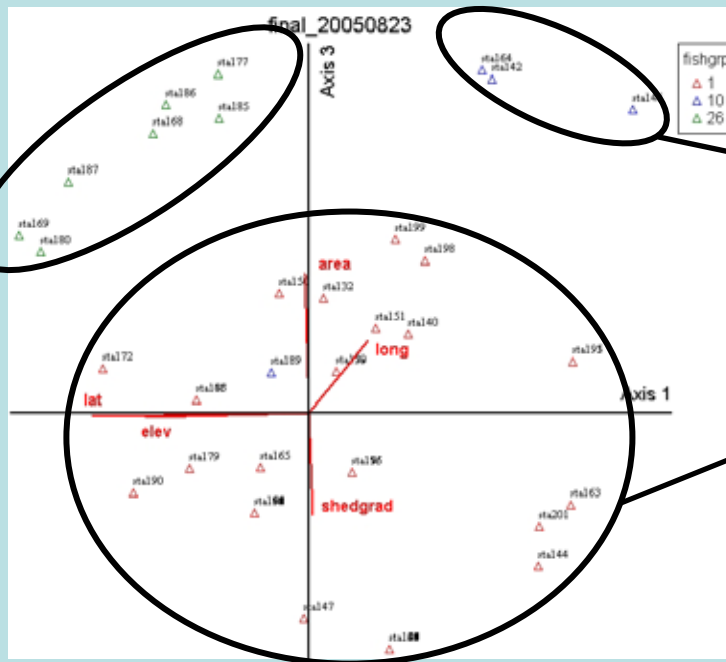

# Dataset

- NH DES biomonitoring fish collections 1997 – 2006
- Limited to 1<sup>st</sup> – 4<sup>th</sup> order streams sampled from June – August
- 163 stations included in analysis (eliminated sites known to have significant human disturbance)
- Broken in calibration (115 sites) and validation (48 sites) datasets
- Analysis based on presence / absence occurrence
- A minimum of 2 individuals collected at site to be considered “present”

# Approach

**Basic premise:** biological assemblages are, in part, structured by the physical and chemical environmental conditions in which they live. If distinct biological assemblages can be identified, then the variables that define them can be determined.

## Identification of assemblage types

Species composition indicated these are coldwater

# Identification of target species

## Requirements for target species:

- ✓ Coldwater “specialists”
- ✓ >30 occurrences
- ✓ known to have statewide distribution
- ✓ native to NH

**Brook Trout (*Salvelinus fontinalis*)**

**Slimy Sculpin (*Cottus cognatus*)**

# Defining the Variables that Structure Coldwater Fish Assemblages

## Requirements

- **Permanence** – Variables that resist change

*Good Example:* Elevation

*Bad Example:* Substrate composition

- **Ease of collection** – Variables that can be obtained quickly, accurately

*Good Example:* Latitude

*Bad Example:* Flood prone width

- **Natural range of variability** – Variables that are robust

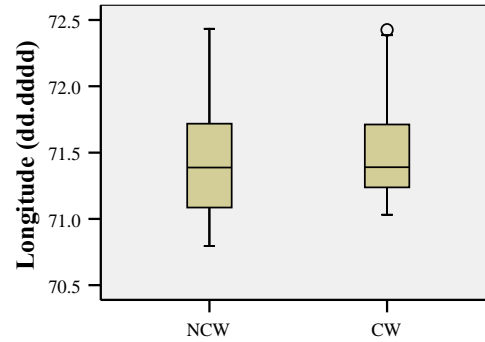

*Good Example:* Watershed size

*Bad Example:* Stream bank slope

## Candidate Variables

- **Latitude** – dd.dddd
- **Longitude** – dd.dddd
- **Elevation** – feet
- **Watershed Area** – square miles
- **Gradient** - % slope
- **Major River Basin** – Merrimack, Piscataqua, Saco, Connecticut, Androscoggin
- **Ecological Drainage Unit (EDU)** – Androscoggin, Upper CT, Lower CT, Merrimack/Coastal

# Independent Consideration of Variables

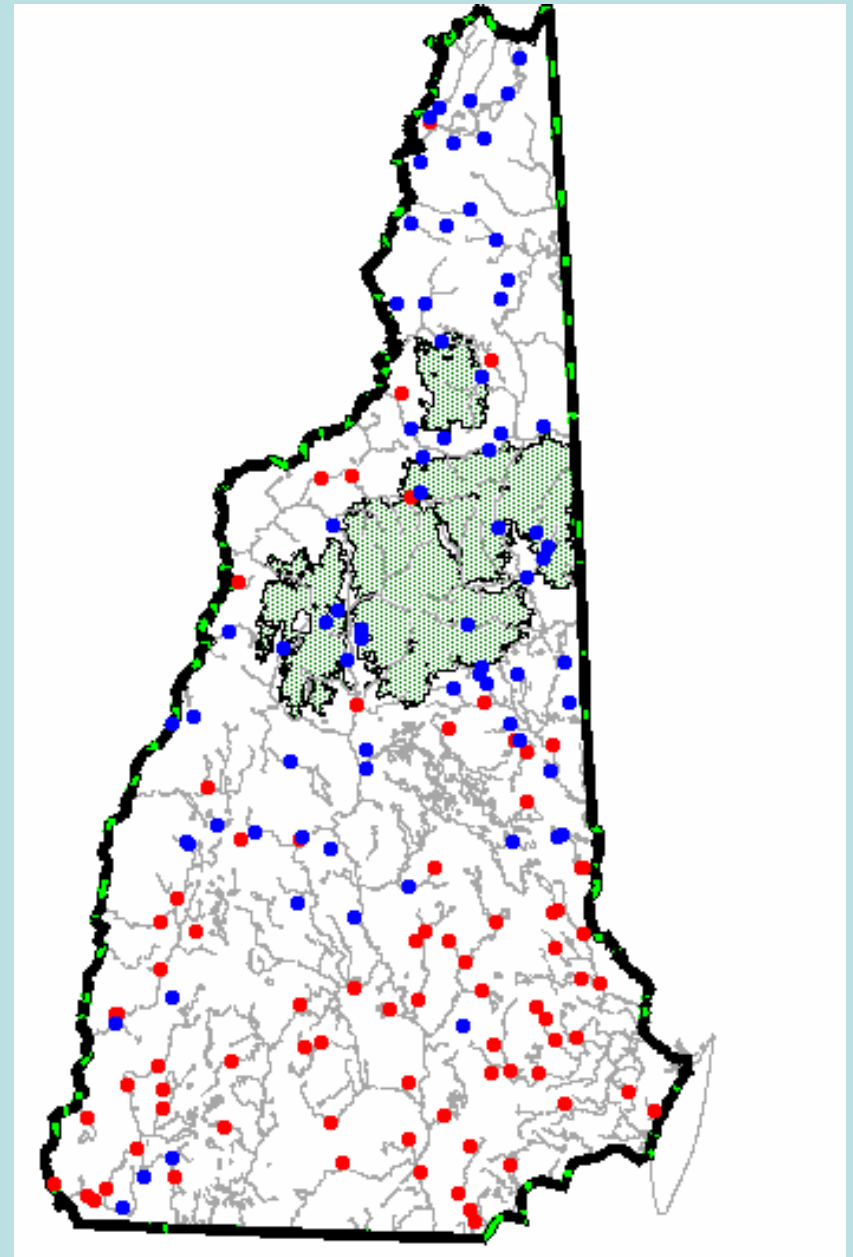

## Results

Variable	Significance
<b>Continuous</b>	
Latitude	<0.001
Longitude	0.396
Drainage Area	<0.001
Elevation	<0.001
Gradient	<0.001
<b>Categorical</b>	
River Basin	<0.005
EDU	<0.005

## Distribution of calibration dataset cold and non-cold water fish assemblages sampled by NH DES biomonitoring unit 1997 – 2006.

- CW community present
- CW community absent
- WMNF Boundaries

- More frequent in north
- More frequent in smaller watersheds
- Less frequent in Merrimack and Coastal areas
- More frequent in steeper gradients
- More frequent at higher elevations

## Simultaneous Variable Consideration

**OK – So 5 of 6 variables show differences b/t cold and non-cold water fish communities, but how do the variables inter-relate?**

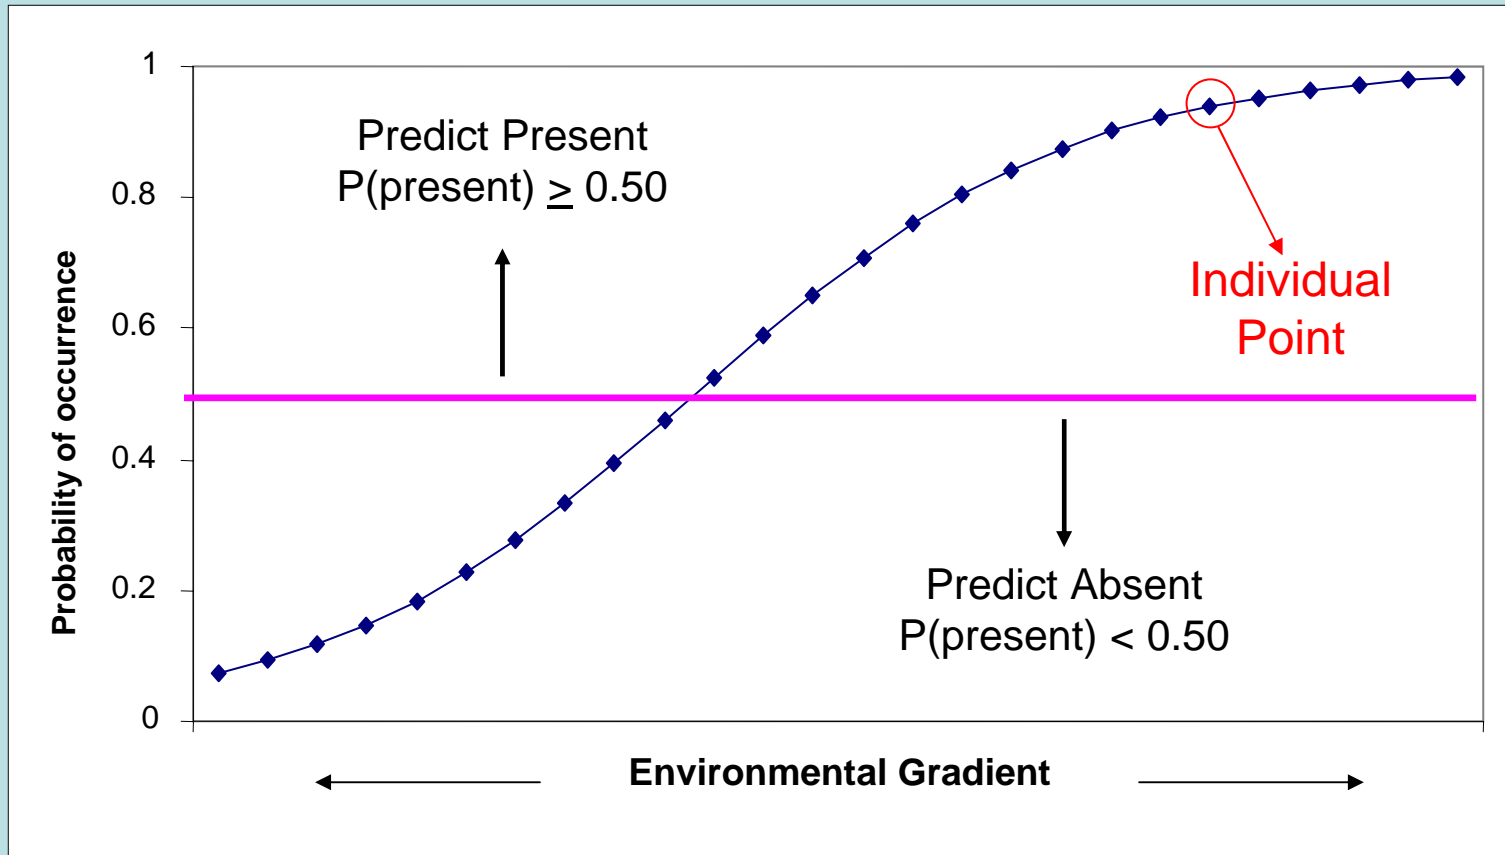

*We need another analysis tool...*

**Logistic Regression: yes, I'll spare you the details**

**What you need to know:**

- **Each variable is examined for its relative importance (similar to step-wise linear regression)**
- **Regression equation assigns each site a probability (0 – 1) of being a cold (1) or non-cold (0) water fish community based on important variables**
- **Predictive accuracy (i.e. # correct predictions) of model as measure of success**

# Logistic Regression Overview

$$P(\text{present}) = \frac{1}{1 + \exp(-\alpha - \beta_1 X_1 - \dots - \beta_i X_i)}$$

## Model Results

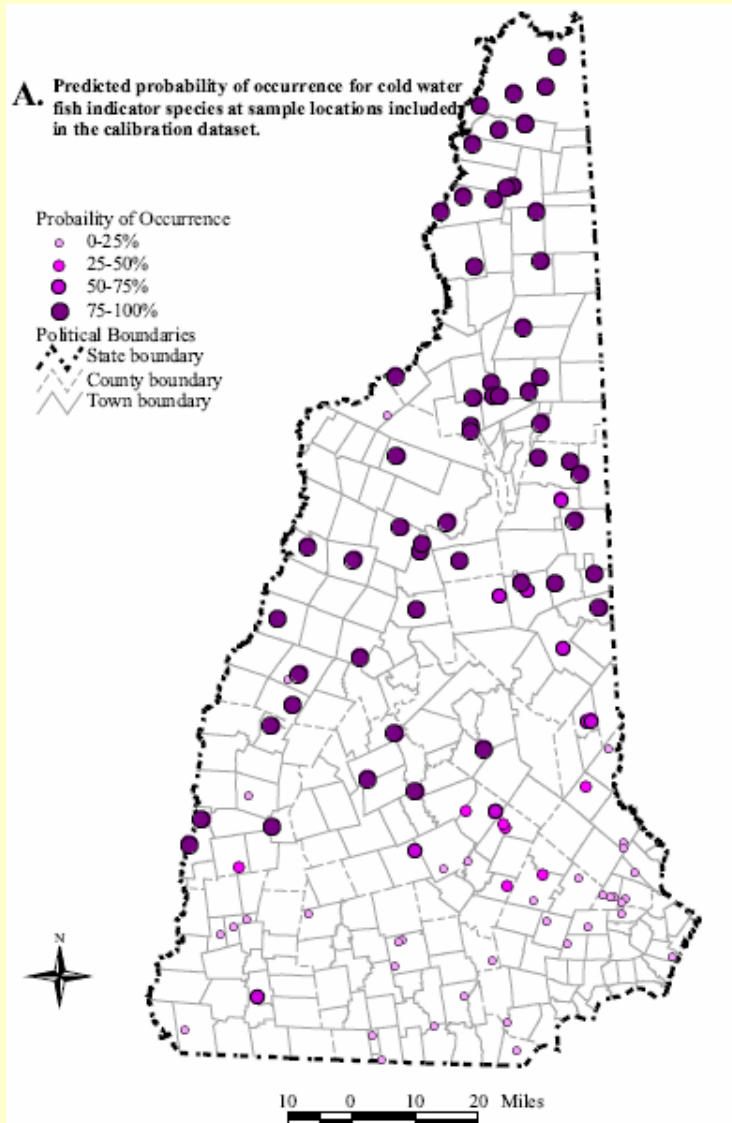

Model #	Variables	Overall Predictive Accuracy
1	Elevation	75.7%
2	Elevation, Drainage Area	82.6%
3	Elevation, Drainage Area, Latitude	83.5%
4	Elevation, Drainage Area, Latitude, Longitude	84.3%
5	Latitude <sup>1</sup> , Drainage Area <sup>2</sup> , Longitude <sup>3</sup>	89.9% (92% present; 86% absent)

# Environmental Gradient

**Increasing probability of occurrence as move from  
SE to NW and decreasing drainage area**

## Calibration Sample Locations

## Statewide Application of Model

Maximum Drainage Area Expected to Support Coldwater Fish Species

Small  
Big

# Exploring Predictive Errors (No Model is Perfect!)

Observed Absent

$P(\text{occur}) > 0.50$ ;  
Predict Present

**Type I** – Reject null hypothesis when it is true

**For model** – predicting CW present when observed absent (6%-cal; 10%-val)

Observed Present

$P(\text{occur}) < 0.50$ ;  
Predict Absent

**Type II** - Do not reject null hypothesis when false

**For model** – predicting CW absent when observed present (5%-cal;6%-val)

**ERRORS**

50%  
Prob. Is a  
balanced  
approach

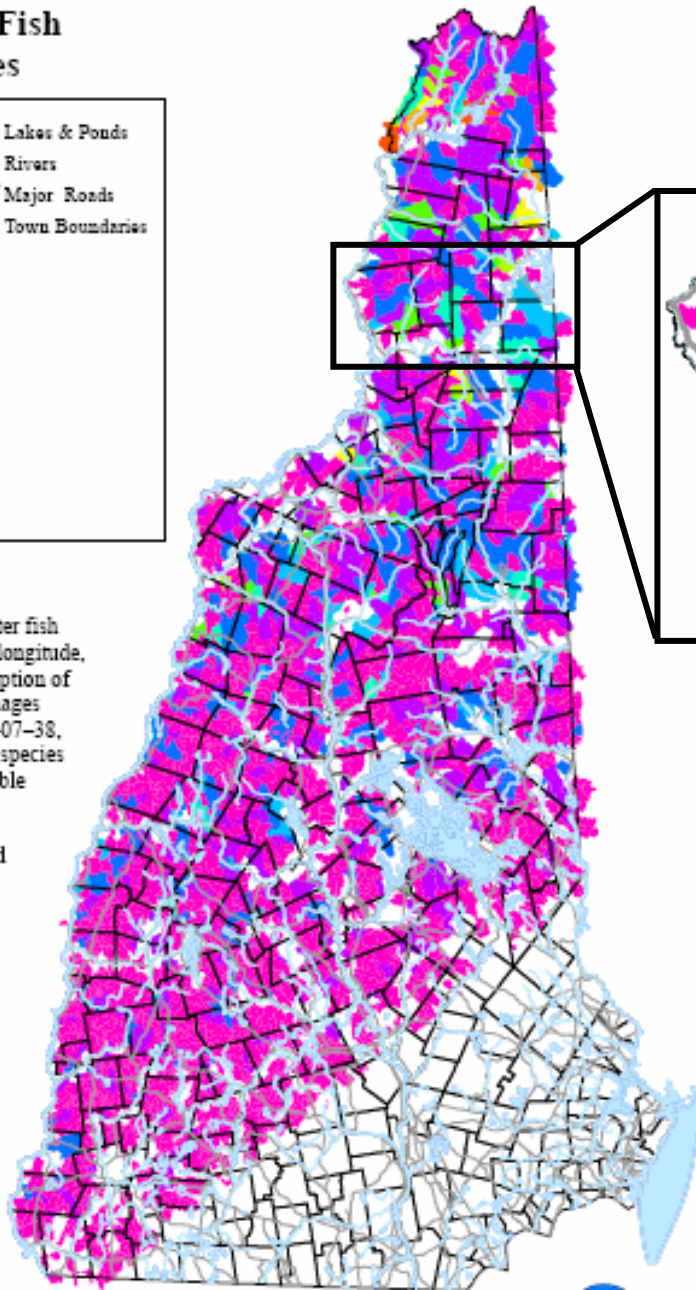

## Expected Coldwater Fish Assemblage Drainages

### Drainage Area-Specific Expected Occurrences

### Notes:

1. Drainage areas of expected coldwater fish assemblages are based on latitude, longitude, and drainage area. For a full description of the determination of expected drainages see NH DES publication # R-WD-07-38, "Predicted coldwater fish indicator species presence in New Hampshire wadeable streams", 2007.
2. Drainage areas based upon the 1:100,000 NHD catchments derived for the USGS, SPARROW model (USGS SIR 2004-5012).

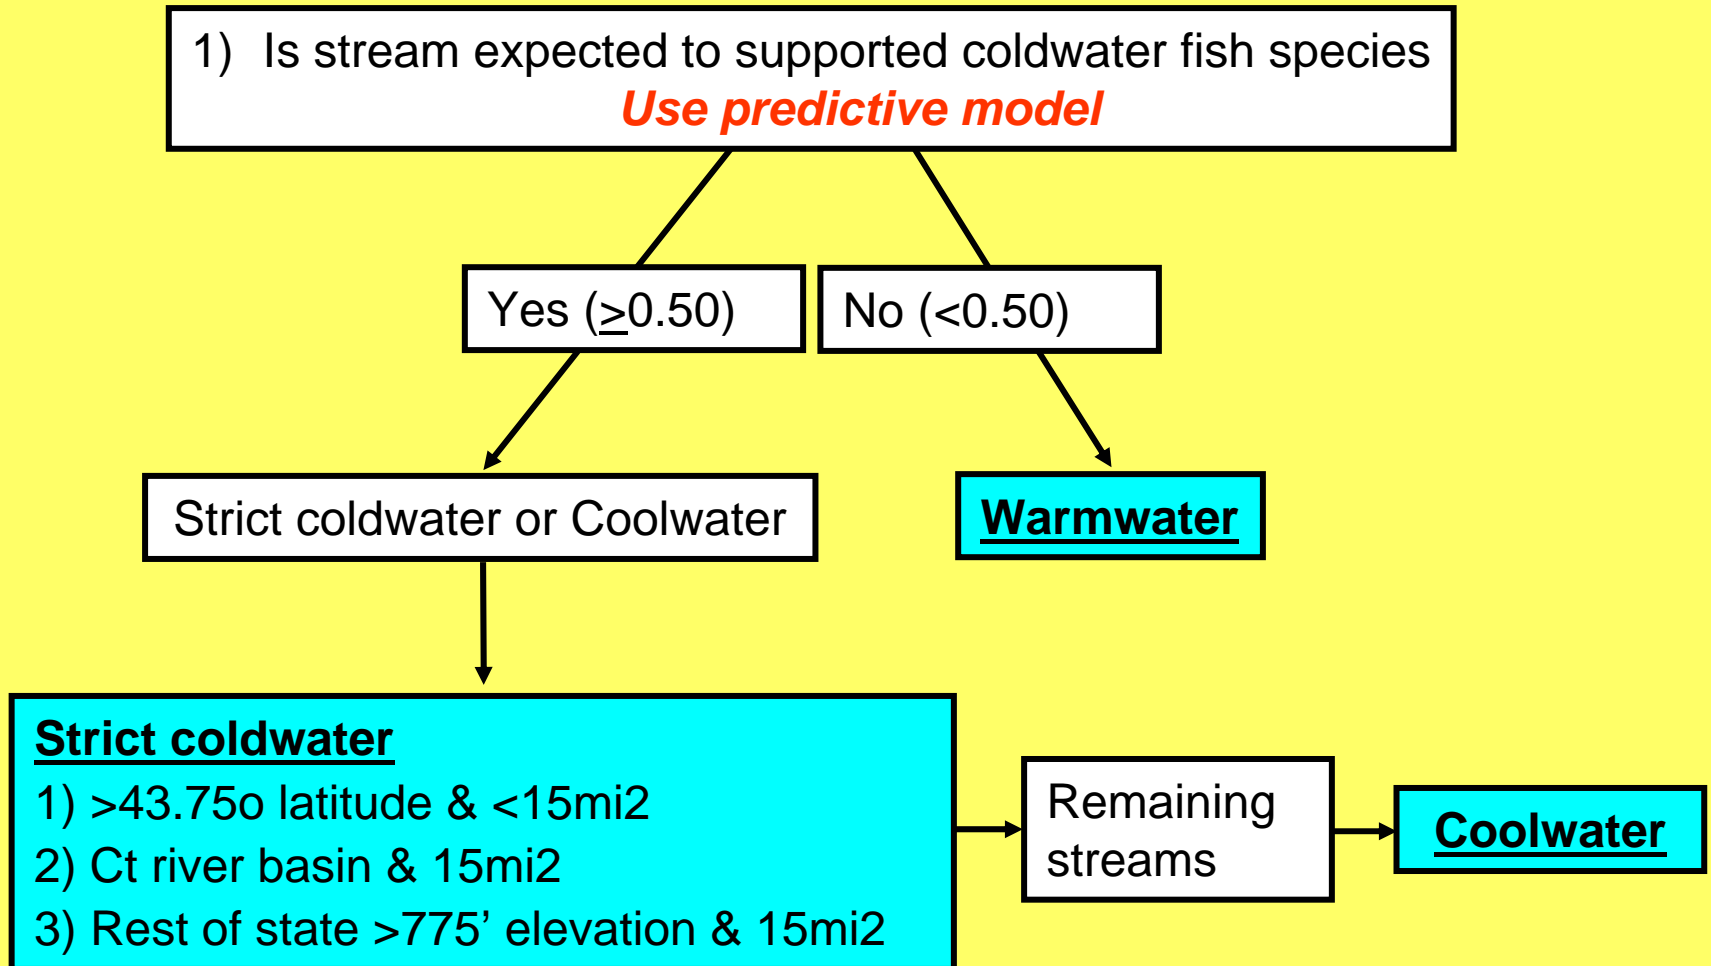

## Expected Drainages Supporting Coldwater Fish Species

- Small drainages most dominant
- Larger drainages in north
- Warmwater streams in white
- Provides definition of streams where coldwater dissolved oxygen criteria should be applied

# Use in Defining Fish Assemblage Types

DES has defined 3 fish assemblage types: Strict Coldwater, Coolwater, Warmwater

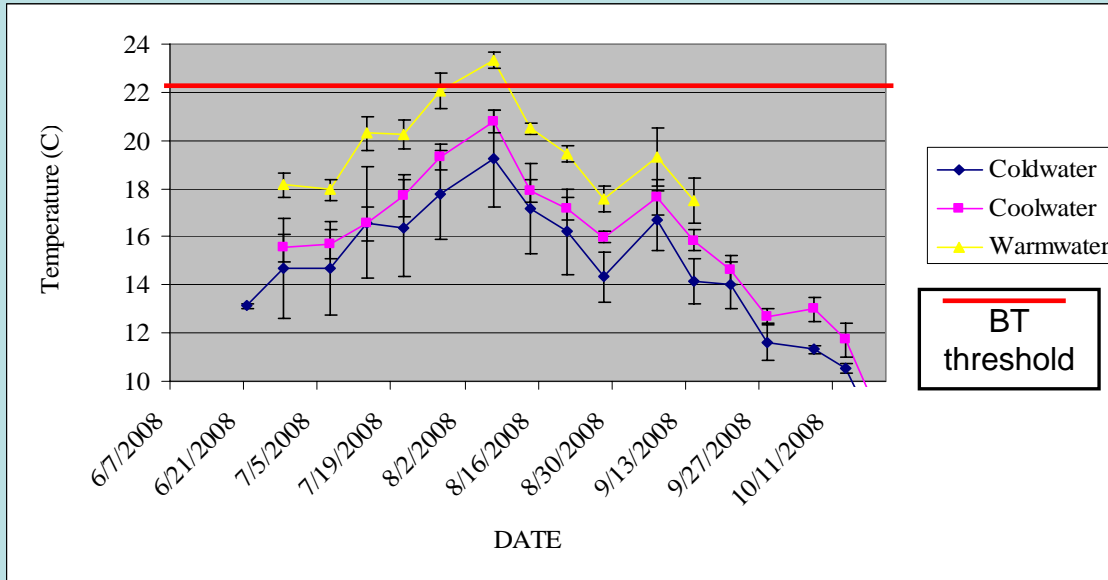

# Expected Fish Assemblage Types by Drainage

# Correspondence With Water Temperature

(Lets not forget what we're talking about)

## 2006/07 Data

- Weekly mean
- Clear separation throughout summer
- Cold and cool below thermal thresholds (BT - 22.3°C, Eaton 1995)
- Coolwater ~1° warmer
- Warmwater ~3° warmer

## 2007 Field Data Verification

**2007 field data:** 18 sites sampled; 15 sites followed modeled predictions (83%) for fish community type

**Why not perfection?** Model predictions are based on undisturbed sites (lack of predicted fish community type may indicate “impact”)

## Summary

- Model provides a-priori “tool” for determining ability to support coldwater fish assemblage (~85% accuracy)
- Latitude, drainage area, and longitude most effective unchanging environmental variables for predicting ability to support coldwater fish assemblages; latitude strongest predictor
- Model establishes southeast to northwest gradient for expected presence; tempered by drainage area
- 50% probability of occurrence minimizes predictive errors; balances Type I and Type II (model is neither too conservative nor liberal)
- Identification of drainages where coldwater DO criteria should be implemented
- Model allows for identification of expected fish assemblage types for development / application of appropriate of biological indices
- Recent water temperature data and fish sampling results provide confirmation of model predictions
- Future work should include continued model verification and determination of the utility of additional predictive variables (i.e. groundwater)
