FA = Fraction Absorbed Water
Kp = Dermal Permeability Coefficient of Compound in Water

T(event) = Event Duration
Tau = Lag Time

T* = Time to Reach Steady-State
B = Dimensionless Ratio of the Permeability Coefficient of a Compound Through the Stratum Comeum Relative to its Permeability Coefficient Across the Viable Epidermis

FA = Fraction Absorbed Water
Kp = Dermal Permeability Coefficient of
Compound in Water

T(event) = Event Duration
Tau = Lag Time

T* = Time to Reach Steady-State
B = Dimensionless Ratio of the Permeability Coefficient of a Compound Through the
Stratum Comeum Relative to its Permeability Coefficient Across the Viable Epidermis

119												
120	Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!											
121	Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!											
122	The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).											
123												
124	The data set for variable Naphthalene was not processed!

143												
144	Warning: There are only 3 Distinct Detected Values in this data set											
145	The number of detected data may not be adequate enough to perform GOF tests, bootstrap, and ROS methods.											
146	Those methods will return a 'N/A' value on your output display!											
147												
148	It is necessary to have 4 or more Distinct Values for bootstrap methods.											
149	It is recommended to have 10 to 15 or more observations for accurate and meaningful results and estimates.

Leachate Samples¹: Landfill and Unnamed Island

Scenario Timeframe:	Current/Future
Exposure Area:	Landfill
Exposure Medium:	Leachate
Receptor(s):	Trespasser, Recreational User
Pathway(s):	Dermal

Location ID Sample ID	Date Collected

Note:

(1) Because there are no "true" leachate data for the site, as discussed, groundwater data will be used as a surrogate to evaluate potential leachate exposures to the trespasser and recreational user. Screening of leachate data using samples below was performed (see Table 2.10) and COPCs were used with the surrogate groundwater data to calculate EPCs.

Subject:

Petersen Puritan Air Modeling

ARCADIS BBL estimated ambient air concentrations for constituents of potential concern (COPC) at the Petersen/Puritan, Inc. Superfund Site (the site) to support the Human Health Risk Assessment (HHRA) for Operable Unit 2 (OU2). COPC concentrations were estimated at discrete distance intervals from passive gas vents located on the J.M. Mills Landfill (the landfill) using analytical data from ambient air grab samples and conservative exposure assumptions in the USEPA SCREEN3 air dispersion model. The results of the analysis indicate that COPC concentrations in ambient air generally decrease with increasing distance from the vents. Given that these results are based on conservative exposure assumptions, these results likely contribute to an overestimate of potential exposure on the landfill.

Site Setting

The site is located in the town of Cumberland along the Blackstone River in Providence County, Rhode Island. The site is approximately two miles long and extends 2,000 feet to the east and west of the main river channel. The site includes an industrial park, an inactive landfill and solid waste transfer station, sand and gravel operations, part of a National Heritage Corridor and state park, municipal water supply wells, and a number of undeveloped areas along the river.

This analysis evaluates potential ambient air concentrations above the landfill. The landfill covers approximately 36 acres and is bounded on the east by the Providence and Worcester Railroad and on the

west by the river. The landfill is greater than 80 feet in elevation at its crest, with steep slopes that are covered with vegetation.

Meteorological data obtained from the National Oceanic and Atmospheric Administration (NOAA) National Climatic Data Center (NCDC) for the Pawtucket, Rhode Island weather station indicate that winds generally blow from the southwest, west or north in the vicinity of the site (NCDC 2007).

Methods

Ambient air concentrations were estimated using the USEPA SCREEN3 model. SCREEN3 is a single source Gaussian plume model which provides maximum ground-level ambient air concentrations for point, area, flare, and volume sources. SCREEN3 can also generate concentration estimates for the cavity zone in building downwash scenarios, and concentrations due to inversion break-up and shoreline fumigation. SCREEN3 is a screening version of the Industrial Source Complex model, Version 3 (ISC3). SCREEN3 assumes that the constituents do not undergo chemical transformation, and no other removal processes, such as wet or dry deposition, act on the plume during transport (USEPA 1995).

Table 1 presents the SCREEN3 model input parameters used for this analysis. Limited data were available to characterize the landfill vents. Shields Environmental Associates, Inc. (Shields) indicates that vent height ranges from ground surface to approximately 3 feet, and inside vent diameter is 4 inches (pers. comm., J. Knauss, May 1, 2007). Default values were used for stack gas temperature (298 K) and ambient gas temperature (293 K). Receptor height (1.75 m or 5.7 ft) above ground was estimated using professional judgment for standard breathing zone height.

Landfill vent gas flow rate was estimated based on the range of values provided in the literature. Two studies present landfill gas flow rates (Kleinfelder 2006; Gebert and Groengroeft 2006). Kleinfelder (2006) reports gas flow rates from passive vents at the Old Southington Landfill Superfund Site in Connecticut ranging from 0.088 ft³/min (0.00042 m³/sec) to 16.1 ft³/min (0.00760 m³/sec). Gebert and Groengroeft (2006) report gas flow rates from biofiltered passive vents at a harbor sludge disposal landfill in Hamburg, Germany ranging from -4 m³/hr (-0.001 m³/sec) to 4 m³/hr (0.001 m³/sec). As noted by Gebert and Groengroeft (2006) passive emission rates of landfill gas are influenced by the pressure gradient between the landfill and the atmosphere, and as such these rates are sensitive to local conditions. Therefore, the rates from the Old Southington Landfill in Connecticut were considered more representative of potential emission rates for the Petersen Puritan landfill, located in Rhode Island, than the landfill located in Germany. For conservatism, the maximum reported gas emission rate from the Old Southington Landfill was selected for this analysis.

Site-specific gas emission rates from landfill vents were unavailable. Emission rates were therefore estimated using the landfill vent gas flow rate and the analytical results of ambient air grab samples collected by Shields in October 2003 near three vents located near the crest of the landfill (AR001-LF,

ARFD-1, AR002-LF, AR003-LF). Half detection limits were used for COPCs that were not detected in air grab samples. Emission rates for each vent were estimated using the following equation:

$$ER = EC * CF * GFR$$

where:

ER = emission rate (g/sec)

EC = air emission concentration (ug/m³)

CF = conversion factor (10⁻⁶ g/ug)

GFR = gas flow rate (m³/sec)

Model assumptions include a single point emission source for a “representative stack.” The USEPA (1992) *Screening Procedures for Estimating the Air Quality Impact of Stationary Sources, Revised* recommends merging emissions parameters for multiple stacks with similar parameters. As the vents on the Petersen Puritan landfill occupy an area less than 100 m in linear distance and have similar construction, emission rates from each vent were summed to generate the emission rates used for each COPC in the model. These point emission rates are presented in Table 2.

Given the environmental setting for the landfill, particularly the distance to buildings and other urban structures, rural dispersion coefficients were used in the model, and no building downwash was assumed.

The landfill vents are located near and just below the crest of the landfill. The crest may exceed vent openings by up to approximately 10 feet within a lateral distance of 20 to 30 feet from the vents. This scenario was modeled using the complex terrain option in SCREEN3. Complex terrain scenarios are utilized for scenarios in which terrain elevations exceed stack height. In these calculations, receptor height is assumed to be at ground surface on the elevated terrain.

Flat terrain was also modeled, assuming full meteorology (i.e., the model evaluates potential plume concentrations for each stability class and associated wind speeds) for distances from the “representative stack” of 1 to 650 meters (m). The nearest fenceline to the vents is located approximately 90 m to the northeast. The farthest fenceline to the vents is located approximately 650 m to the northwest.

Results

SCREEN3 outputs include the maximum modeled 1-hour concentration across stability classes for each distance modeled from the source (USEPA 1995).

The results of the complex terrain modeling indicate that plume height is less than the terrain height at the crest of the landfill. As such, modeled exposure to receptors at ground surface on the crest of the landfill is negligible.

Flat terrain model results for each COPC are presented in Attachment A. The results indicate that maximum concentrations are present nearest the source (the vents); concentrations decrease as distance increases laterally toward the fenceline and away from the vent location.

The results from the flat terrain scenario were assumed to represent COPC concentrations on concentric circles radiating out from the “representative stack,” which was assumed to occupy the location of the central vent, Vent 3 (Figure 1). Modeled concentrations for locations within the area of the landfill were used to estimate reasonable maximum exposure (RME) and central tendency exposure (CTE) ambient air concentrations across the landfill.

RME ambient air concentrations for the landfill were estimated by averaging modeled 1-hour maximum concentrations for points within the landfill along the approximate four cardinal (North, South, East, West) and four intercardinal (Northeast, Southeast, Southwest, Northwest) directions at each modeled distance from the plume. Figure 1 presents approximate locations for the modeled air concentration locations included in the RME ambient air concentration calculations (in red). RME exposure point concentrations are presented in Table 3.

CTE ambient air concentrations for the landfill were estimated by multiplying the RME ambient air concentration by a factor of 0.7 to estimate the maximum 8-hour concentration across the landfill. USEPA (1992) recommends the use of this factor to convert 1-hour maximum concentrations into 8-hour maximum concentrations. CTE exposure point concentrations are presented in Table 3.

Uncertainty Assessment

The input parameters for the model are generally conservative, and likely contribute to an overestimate of exposure. Specifically, the use of the maximum reported landfill gas flow rate is a conservative estimate of emission rates. The relationship between atmospheric pressure and landfill gas emission rates has been documented in the literature (GC Environmental 1985; Gebert and Groengroeft 2006). In general, landfill internal pressure increases and decreases in response to atmospheric pressure. As such, landfill gas flow rates are inversely related to atmospheric pressure. As atmospheric pressure decreases, landfill gas pressure and landfill gas flow rates may increase. Conversely, landfill gas flow rates may decrease during periods of increasing atmospheric pressure, and may cause a temporary infiltration of ambient air into the landfill (GC Environmental 1985). Gebert and Groengroeft (2006) documented changes in gas flux direction on average every 20 hours (i.e., more than once a day). The authors concluded gas emissions were driven by momentary pressure buildups inside the landfill, conditions which were not sustained for long periods of time (Gebert and Groengroeft 2006). Given the fluctuating nature of landfill

gas emission rates, the use of a maximum landfill gas flow rate to model long-term ambient air conditions produces a highly conservative estimate of exposure.

Model results for the crest of the landfill indicate that exposure to receptors at ground surface is negligible. Winds generally come from the southwesterly to northerly direction in the vicinity of the site. As such, the direction of vent plumes, if any, is anticipated to be toward the northeast to south, and away from the crest of the landfill. Therefore, uncertainty regarding modeled exposure to receptors at the crest of the landfill likely contributes to an overestimate of exposure.

Model results for flat terrain also contribute to an overestimate of exposure. The location of the vents is at the crest of the landfill. The slopes of the landfill are steep. Therefore, receptors located at the base of the landfill may be located below the plume, where actual ambient air concentrations of COPC may be less than modeled concentrations. As such, the uncertainty associated with the use of flat terrain calculations likely contributes to an overestimate of potential exposure to receptors below the crest of the landfill, on the landfill property, or at the property fenceline.

Notes:

COPC = constituent of potential concern

RME = reasonable maximum exposure

CTE = central tendency exposure

RME concentration estimated by averaging concentrations for concentric ring points within the area of the landfill. See Figure 1 for locations.

CTE estimated by multiplying RME concentration by factor of 0.7 to convert to average of 8-hour maximum concentrations.

Grey locations excluded from average.
Red locations included in average.
Modeled locations are approximate.

February 7, 2007ARCADIS BBL Project No.:
37902.300Subject:
Peterson Puritan Risk Assessments: Statistical Evaluation of Fish Tissue PCB Data
for OU2 and Upstream/Background Areas

The following briefly describes the fish sampling program, and presents the methodology and results of statistical evaluations (i.e., analysis of variance) conducted for the fish tissue PCB homolog data collected as part of the Remedial Investigation. The objective of the evaluation was to determine if there are statistically significant differences in fish tissue PCB homolog concentrations for fillet and whole-body fish samples collected from various portions of the Blackstone River, OU2 ponds and a background/reference area pond.

Fish Sampling:

Fish fillet samples of largemouth bass, white sucker, bluegill and pumpkinseed were collected to evaluate potential human health exposures. Fillet samples were intended to represent edible-size fish that could be consumed by local anglers. Composite whole-body fish samples of common shiner, golden shiner, bluegill and pumpkinseed were collected to evaluate potential ecological exposures. Additionally, whole-body PCB concentrations for largemouth bass and white suckers were calculated by summing concentrations for fillet and remaining carcass samples.

Fish data were collected from the following locations (in order from upstream to downstream) (see Figure 1):

P-6: Isolated background pond located north of site (OU2)

BR-1: Stretch of Blackstone River located upstream of Ashton Dam

BR-2: Stretch of Blackstone River located downstream of Ashton Dam

BR-3: Stretch of Blackstone River located adjacent to the site (OU2); terminus is Pratt Dam

P-1 (Pond A): Pond located within the Unnamed Island within OU2

P-2 (Pond F): Pond located within OU2, adjacent to Pratt Dam

The following table presents a summary of the fish species and sample types collected from the Blackstone River and OU2 ponds, as well as the background pond.

Fish Species	Sample Type	Sampling Location	Sample Size
Largemouth bass	Fillet	BR-2	8
		BR-3	8
		P-1	8
		P-6	8
	Whole-body ^a	BR-2	8
		BR-3	8
		P-1	8
		P-6	8
White sucker	Fillet	BR-1	8
		BR-2	8
		BR-3	8
		P-1	8
		P-2	8
	Whole-body ^a	BR-1	8
		BR-2	8
		BR-3	8
Bluegill	Fillet	BR-1	5
		P-2	7
	Whole-body ^a	BR-1	5
		P-2	7
	Whole-body composite ^b	P-1	8
		P-6	8
Pumpkinseed	Fillet	BR-1	3
		P-2	1
	Whole-body ^a	BR-1	3
		P-2	1

Fish Species	Sample Type	Sampling Location	Sample Size
Common shiner	Whole-body composite ^b	BR-1	8
		BR-2	8
		BR-3	8
Golden shiner	Whole-body composite ^b	P-2	8

Notes:

^a Whole-body PCB concentrations were calculated by summing fillet and remaining carcass concentrations.

^b Represents whole-body composite samples.

Methodology:

The statistical evaluation of fish PCB homolog data consisted of Analysis of Variance (ANOVA), which is a statistical method for making simultaneous comparisons between two or more data sets (e.g., groups, populations) to determine if there is a statistically significant difference between them. An analytical software package (Statistix 7) was used to run the ANOVAs. Prior to analysis, the fish data were separated into species and sample type (i.e., fillet, whole-body), and in some instances, size ranges if sufficient data were available. Subsequently, the data sets were tested for normality to determine if they follow a certain distribution (i.e., normal, lognormal, non-parametric).

A parametric One-Way Analysis of Variance (AOV) was conducted for data sets that followed a normal or lognormal distribution. The output of the One-Way AOV is a p-value, which indicates whether the null hypothesis (i.e., concentrations are not significantly different between groups) should be accepted or rejected. Following the One-Way AOV, a Bonferroni Comparison of Means (alpha = 0.05) was used to compare the means of the different groups. The output of the Comparison of Means is a tabular presentation of homogeneous populations.

For non-parametric data sets (i.e., those that don't follow a certain pattern), the Kruskal-Wallis One-Way AOV procedure was used, which relies on a ranking system to determine if there are significant differences in central values (i.e., medians) between groups. Like the One-Way AOV, the output of the Kruskal-Wallis One-Way AOV is a p-value, which indicates whether the null hypothesis (i.e., concentrations are not significantly different between groups) should be accepted or rejected. Following the Kruskal-Wallis One-Way AOV, a Comparison of Mean Ranks (alpha = 0.05) was used to compare the mean ranks of the different groups. Like the Bonferroni Comparison of Means, the output of the Comparison of Mean Ranks is a tabular presentation of homogeneous populations.

Analyses were performed on both lipid-normalized and un-normalized PCB homolog fish tissue data.

Results for Fish Fillets:

Largemouth Bass

- There are no statistically significant differences in fish tissue PCB concentrations in largemouth bass (all sizes) collected from BR-2, BR-3 and P-1. However, fish tissue PCB concentrations in largemouth bass from P-6 (background pond) are significantly lower compared to concentrations observed in largemouth bass from the Blackstone River with the following exception: lipid-normalized PCB concentrations in bass from P-6 are not significantly lower than lipid-normalized PCB concentrations in bass from BR-2.
- There are no statistically significant differences between largemouth bass (>30 cm in length) PCB concentrations collected from BR-3 and P-1. However, PCB concentrations in largemouth bass of this same size range collected from P-6 are significantly lower than those PCB concentrations in bass from BR-3 and P-1. Lipid-normalized PCB data displayed the same results.

Bluegill/Pumpkinseed

- There are no statistically significant differences in fish tissue PCB concentrations in bluegill and pumpkinseed (all sizes) collected from BR-1 and P-2. However, the evaluation of lipid-normalized PCB data for these species showed a significant difference between BR-1 and P-2.

White Sucker

- There are no statistically significant differences in fish tissue PCB concentrations in white suckers (all sizes) collected from BR-2, BR-3, P-1 and P-2. Similarly, white sucker PCB concentrations from BR-1, P-1 and P-2 are not significantly different. Evaluation of the lipid-normalized PCB data showed no statistically significant differences in white sucker concentrations from BR-2, BR-3 and P-2. Likewise, lipid-normalized PCB concentrations from BR-1, BR-3, P-1 and P-2 are not significantly different.
- There are no statistically significant differences in fish tissue PCB concentrations in white suckers (>35 cm in length) collected from BR-1, BR-2 and BR-3. Lipid-normalized PCB data displayed the same results.

The following tables summarize the above results for fish fillet PCB concentrations (un-normalized and lipid-normalized data). Populations with "I" in the same column are not significantly different from one another, while populations with "I" in separate columns are significantly different from one another.

Total PCB Homologs: Fish Fillets			
Species	Size	Location	Homogeneous Populations ⁽¹⁾
Largemouth bass	All ⁽³⁾	BR-2	
		BR-3	
		P-1	
		P-6	
	>30 cm ⁽³⁾	BR-3	
		P-1	
		P-6	
Bluegill/Pumpkinseed	All ⁽²⁾	BR-1	
		P-2	
White sucker	All ⁽³⁾	BR-1	
		BR-2	
		BR-3	
		P-1	
		P-2	
	>35 cm ⁽³⁾	BR-1	
		BR-2	
		BR-3	

Total PCB Homologs (Lipid-Normalized): Fish Fillets			
Species	Size	Location	Homogeneous Populations ⁽¹⁾
Largemouth bass	All ⁽³⁾	BR-2	
		BR-3	
		P-1	
		P-6	
	>30 cm ⁽³⁾	BR-3	
		P-1	
		P-6	
Bluegill/Pumpkinseed	All ⁽²⁾	BR-1	
		P-2	
White sucker	All ⁽²⁾	BR-1	
		BR-2	
		BR-3	
		P-1	
		P-2	
	>35 cm ⁽²⁾	BR-1	
		BR-2	
		BR-3	

Notes:

(1) Based on comparison of mean ranks using Statistix 7.0. Populations with "I" in the same column are not significantly different from one another. Conversely, populations with "I" in different columns are significantly different from one another. Results should be interpreted on a species-specific basis.

(2) Sample populations for the white sucker locations were shown to be either normal- or lognormally-distributed. One way Analysis of Variance (AOV) methods were used to test differences in sample populations. Comparison of means were performed using the Bonferroni test methodology for an alpha value equal to 0.05.

(3) Sample population comparisons were performed using Kruskal-Wallis AOV non-parametric test; based on statistical differences (at alpha = 0.05) of the mean ranks.

Results for Whole-Body Fish:

Bluegill/Pumpkinseed

- There are no statistically significant differences in fish tissue PCB concentrations in bluegill and pumpkinseed (all sizes) collected from BR-1 and P-2. PCB concentrations in bluegill and pumpkinseed from P-1 and P-6 are significantly different from one another, and are also significantly different compared to BR-1 and P-2. The evaluation of lipid-normalized PCB data for these species showed a significant difference between all groups (i.e., BR-1, P-1, P-2 and P-6).

Common Shiner/Golden Shiner

- There are no statistically significant differences in fish tissue PCB concentrations in shiners from BR-1, BR-2 and BR-3. Likewise, there are no statistically significant differences in PCB concentrations in these species collected from BR-3 and P-2. The evaluation of lipid-normalized PCB concentrations showed no statistically significant differences in fish tissue PCB concentrations from BR-2, BR-3 and P-2. Likewise, lipid-normalized PCB concentrations in fish from BR-1, BR-2, and P-2 are not significantly different from one another.

Largemouth Bass

- There are no statistically significant differences in fish tissue PCB concentrations in largemouth bass (all sizes) collected from BR-2, BR-3 and P-1. Likewise, there are no statistically significant differences in fish tissue PCB concentrations from P-1 and P-6. The evaluation of lipid-normalized PCB concentrations in fish showed no statistically significant differences between BR-2, BR-3 and P-1; however, lipid-normalized PCB concentrations in fish from P-6 were significantly lower compared to BR-2, BR-3 and P-1.

- There are no statistically significant differences between largemouth bass (>30 cm in length) PCB concentrations collected from BR-3 and P-1. However, PCB concentrations in largemouth bass of this same size range collected from P-6 are significantly lower than PCB concentrations in bass from BR-3 and P-1. Lipid-normalized PCB data displayed the same results.

White Sucker

- There are no statistically significant differences in fish tissue PCB concentrations in white suckers (all sizes) collected from BR-2 and BR-3. Similarly, white sucker PCB concentrations from BR-3 and P-2 are not significantly different. Also, PCB concentrations in fish from BR-1, P-1 and P-2 are not significantly different. Evaluation of the lipid-normalized PCB data showed no statistically significant differences in white sucker concentrations from BR-2, BR-3 and P-2. Likewise, lipid-normalized PCB concentrations in fish from BR-1, BR-3, P-1 and P-2 are not significantly different.
- There are no statistically significant differences in fish tissue PCB concentrations in white suckers (>35 cm in length) collected from BR-1 and BR-3; PCB concentrations in fish from BR-2 were significantly different compared to those concentrations observed in fish from BR-1 and BR-3. However, lipid-normalized PCB concentrations showed there are no statistically significant differences in fish from BR-1, BR-2 and BR-3.

The following tables summarize the above results for PCB concentrations in whole-body fish (un-normalized and lipid-normalized data). Populations with "I" in the same column are not significantly different from one another, while populations with "I" in separate columns are significantly different from one another.

Total PCB Homologs: Whole-Body Fish			
Species	Size	Location	Homogeneous Populations ⁽¹⁾
Bluegill/Pumpkinseed	All ⁽²⁾	BR-1	
		P-1	
		P-2	
		P-6	
Common/Golden Shiner	All ⁽³⁾	BR-1	
		BR-2

		P-2	

Notes:

(1) Based on comparison of mean ranks using Statistix 7.0. Populations with "I" in the same column are not significantly different from one another. Conversely, populations with "I" in different columns are significantly different from one another. Results should be interpreted on a species-specific basis.

(2) Sample populations were shown to be either normal- or lognormally-distributed. One way Analysis of Variance (AOV) methods were used to test differences in sample populations. Comparison of means were performed using the Bonferroni test methodology for an alpha value equal to 0.05.

(3) Sample population comparisons were performed using the Kruskal-Wallis AOV non-parametric test; based on statistical differences (at alpha = 0.05) of the mean ranks.

ARCADIS BBL

Summary:

In general, PCB homolog concentrations in fish collected from OU2 ponds and the portion of the Blackstone River adjacent to the site were not significantly different compared to PCB homolog concentrations observed in fish collected from upstream locations within the Blackstone River.

US EPA ARCHIVE DOCUMENT

1.0 Introduction

As requested by the United States Environmental Protection Agency (USEPA), this technical memorandum presents an evaluation of potential risks associated with exposure of human receptors to lead in site-related media at the Peterson Puritan Operable Unit 2 (OU2) Superfund Site located in Cumberland and Lincoln, Rhode Island. This technical memorandum is included as Appendix Z to the *Baseline Human Health Risk Assessment* (HHRA) that was submitted for the site in February 2009 (ARCADIS, 2009).

Lead was identified as a constituent of potential concern (COPC) in the HHRA (ARCADIS, 2009) for the following subareas and media:

- Site-wide surface soil (excluding Nunes Parcel and wetlands)
- Nunes Parcel surface soil
- Nunes Parcel subsurface soil
- Site-wide sediments
- Wetland sediments
- Site-wide groundwater
- Leachate
- Fish (fillet) tissue

As requested by the USEPA, the lead evaluation consists of a separate evaluation for each subarea of the site and each exposure scenario previously evaluated in the HHRA (ARCADIS, 2009). Although lead was identified as a COPC in leachate, this exposure pathway is not quantitatively evaluated because uncertainty in assigning a dermal absorption fraction for lead precludes quantification of potential risks associated with the dermal exposure route (USEPA, 2003a; 2004; 2007).

2.0 Methodology

Risks associated with exposure to lead in various site-related media were evaluated using USEPA's lead models – the Adult Lead Model (ALM) and the IEUBK Model for Lead in Children (USEPA, 1994a; 2003a). Specifically, the ALM was used to evaluate potential lead risks for non-residential scenarios, and the IEUBK Model was used to evaluate potential lead risks for residential scenarios (i.e., children ages 0 to 84 months of age). Parameter values used in the ALM and IEUBK are largely based on the USEPA's recommended default values and were previously approved by the USEPA on May 13, 2008. The dose equations and modeling approaches are consistent with USEPA guidance (1994a; 2003a; 2007).

Incidental ingestion of lead in soil is generally the primary exposure pathway of concern for risk assessments. However, the models can also quantify cumulative doses and risk attributed to other sources of exposure, such as drinking water, diet, lead-based paint, and air emissions. Because lead is ubiquitous in the environment, predicted blood lead levels (PbB) associated with exposure to site-related sources of lead are added to an assumed age-specific baseline PbB that reflects exposure to non-site-related sources of lead. Forty-one different exposure scenarios (current and future) were evaluated using the ALM, including exposure of recreational users (adults and older children, age 6 to 12 years), commercial workers, construction workers, adolescent trespassers (age 9 to 18 years), and adult anglers. Four exposure scenarios were evaluated using the IEUBK Model: exposure of residential young children to site-wide groundwater, exposure of young children to fish tissue, exposure of residential young children to soil and groundwater at Nunes

Parcel, and exposure of residential young children to soil and groundwater at the Rhode Island Department of Environmental Management (RIDEM) Soil Removal Area.

In both the ALM and IEUBK Model, potential health risks associated with lead exposure are evaluated by comparing the estimated PbB to the target PbB of 10 micrograms per deciliter ($\mu\text{g/dL}$) (Centers for Disease Control [CDC], 1991). The target PbB is based on potentially adverse neurological effects in children (CDC, 1991). Therefore, lead risk is evaluated based on the probability that PbB among a receptor population will exceed 10 $\mu\text{g/dL}$. This is sometimes referred to as the “P10 statistic.” Consistent with USEPA guidance (USEPA, 1994a; 2003b), this lead evaluation focuses on determining if P10 equals or exceeds 5 percent, which is equivalent to calculating the 95th percentile of the probability distribution of PbB among a receptor population.

The USEPA employs a simplifying assumption in both models to estimate the probability distribution of PbBs. Each model first generates a point estimate of the central tendency of the PbB distribution, and it is assumed that the value represents the geometric mean PbB among a receptor population that is exposed to the same levels of lead in the environment. Epidemiological data on PbBs among various populations suggests that the distribution is roughly lognormal in shape (USEPA, 1994b). The USEPA applies the assumption of lognormality to both models using the following equation:

$$PbB_{0.95} = PbB_{GM} \times GSD^{1.645}$$

$PbB_{0.95}$ = 95th percentile of the distribution of PbBs ($\mu\text{g/dL}$)
 PbB_{GM} = geometric mean (or 50th percentile) of the lognormal distribution of PbBs ($\mu\text{g/dL}$)
 GSD = geometric standard deviation of the lognormal distribution of PbBs (unitless)

3.0 Adult Lead Model for Non-Residential Receptor Populations

The USEPA’s ALM is used to evaluate risks to non-residential receptor populations (USEPA, 2007). The following equation is used in the ALM to estimate quasi-steady state PbBs:

$$PbB_{GM} = PbB_0 + \frac{PbS \times BKSF \times IR \times AF \times EF}{AT}$$

PbB_{GM} = geometric mean (or 50th percentile) of the lognormal distribution of PbBs in adult workers ($\mu\text{g/dL}$)
 PbB_0 = baseline PbB due to exposure to non-site-related sources of lead ($\mu\text{g/dL}$)
 PbS = soil lead concentration (milligrams per kilogram [mg/kg])
 $BKSF$ = biokinetic slope factor ($\mu\text{g/dL}$ per micrograms per day)
 IR = soil ingestion rate (grams per day [g/day])
 AF = gastrointestinal absorption fraction for lead in soil (unitless)
 EF = exposure frequency (days per year)
 AT = averaging time (years)

The receptor of concern in the ALM is the fetus of an adult worker. The USEPA assumes a linear relationship between PbB in the adult woman and the fetus. Therefore, the geometric mean PbB in the fetus is equal to PbB_{GM} multiplied by a constant, R. USEPA guidance (2003b) indicates that because the IEUBK Model is limited to 0 to 84 months, the ALM may also be used to assess older children and adolescents with appropriate adjustments. Per the USEPA’s request, a time-

weighted approach was used to evaluate potential risks for recreational users and trespassers consistent with USEPA guidance (2003b).

3.1 Adult Lead Model Parameter Values

Table 1a presents the central tendency parameter values used to evaluate lead risks for the following receptors:

- Current and future commercial worker (risks presented in Table 1b)
- Future construction worker (risks presented in Table 1c)
- Current and future adult recreational user (risks presented in Table 1d)
- Current and future older child recreational user (risks presented in Table 1e)
- Current adolescent trespasser (risks presented in Table 1f)
- Current and future adult angler (risks presented in Table 1g)

Baseline Blood Lead Concentration (PbB₀)

The baseline PbB is intended to represent the best estimate of a reasonable central value of PbB in women of child-bearing age who are not exposed to lead-contaminated non-residential soil or dust at the site. The USEPA (2003b) recommends a range of baseline concentrations (1.7 to 2.2 µg/dL) based on national survey data for women from different demographic groups defined by geographic region, ethnicity, and race. Per the USEPA's request, a baseline value of 1.9 µg/dL was used in the ALM, which represents non-Hispanic white populations from the Northeast Region (USEPA, 2002a).

Geometric Standard Deviation

The USEPA recommends a range of geometric standard deviations (GSDs) that may be used in the ALM Model, depending on site-specific demographics and the characteristics of the receptor population (USEPA, 2003b). Higher GSD values imply greater variability in PbBs and will result in a higher probability of exceeding the target PbB of 10 µg/dL. Per the USEPA's request, a GSD of 2.01 was used in this lead evaluation to reflect a non-Hispanic white population from the Northeast (USEPA, 2002a).

Biokinetic Slope Factor

The Biokinetic Slope Factor (BKSF) represents the increase in typical adult PbB due to average daily lead uptake. The USEPA (2003b) recommends a default value of 0.4 µg lead/dL blood per µg lead absorbed per day for the BKSF. This value is based on empirical data on the relationship between tap-water lead concentrations and PbBs for a sample group of adult males. This default value was used for all exposure pathways in this evaluation.

Soil Ingestion Rate (IR_s)

Consistent with USEPA guidance (2003a; 2007), a soil ingestion rate of 50 mg/day was used to evaluate potential risks for the commercial worker, adult recreational user, older child recreational user, and adolescent trespasser. This value represents the central tendency ingestion rate for soil non-contact-intensive activities (including soil-derived indoor dust) (USEPA, 2007). Per the USEPA's request, a soil ingestion rate of 330 mg/day was used to evaluate potential lead exposures for the construction worker. However, it should be noted that this value is significantly

higher than the central tendency ingestion rate (100 mg/day) recommended by the USEPA (2007) for the construction worker scenario.

Exposure Frequency and Averaging Time

Exposure frequencies used in this lead evaluation were consistent with values used in the HHRA (ARCADIS, 2009). Consistent with USEPA guidance (2003b), a time-weighted average approach was used to evaluate potential risks for recreational users and trespassers.

Lead Absorption Fraction

This evaluation used a lead absorption fraction of 0.12, which is the default value recommended by the USEPA (2003b). This value is based on experimental studies of the bioavailability of ingested lead in adults with considerations for the following three major sources of variability: 1) effect of food on lead bioavailability, 2) nonlinearity in PbB, and 3) effect of lead form and particle size on bioavailability. The value assumes the a relative bioavailability of 0.6 for lead in site-related media as compared to soluble lead, and also assumes an absorption fraction (AF) of 0.2 for soluble lead. Thus, the final AF is 0.12 (i.e., $AF = 0.6 \times 0.2 = 0.12$).

Fetal/Maternal Blood Lead Concentration ($R_{\text{fetal/maternal}}$)

This evaluation used a fetal/maternal blood lead ratio of 0.9 for adult receptors, which is the default value recommended by the USEPA (2003b) based on studies that have explored the relationship between umbilical cord and maternal PbBs. Because the older child recreational user and adolescent trespasser are not of child-bearing age, the fetal/maternal PbB ratio for these receptors was set equal to 1.

Fish Ingestion Rate

For the adult angler scenario, it was assumed that site-related lead exposure is restricted to fish consumption. The lead evaluation used the same Central Tendency Exposure fish ingestion rate (8.9 g/day) as was used in the HHRA (ARCADIS, 2009). This value represents the 50th percentile for fish-consuming anglers in Maine from Ebert et al. (1993). The lead evaluation conservatively assumes that 100 percent of fish consumed by the adult angler are from on-site sources.

3.2 Exposure Point Concentrations

The exposure point concentrations (EPCs) used in the lead evaluation are arithmetic means based on site-related data. As requested by the USEPA, media within each subarea were evaluated separately (i.e., medium-specific arithmetic means were used as the EPCs). Per the USEPA's request, one-half the laboratory detection limit was used as a surrogate for non-detects in calculating arithmetic mean lead concentrations. Attachment A presents the sample groupings used to calculate EPCs for each exposure scenario evaluated using the ALM. Attachment B presents the sample groupings used to calculate EPCs for each exposure scenario evaluated using the IEUBK model.

3.3 Adult Lead Model Results

Table 1b presents the modeling results for the commercial worker. The ALM predicts that exposure of commercial workers to site-related media at Nunes Parcel and Quinnville Wellfield

will result in a P10 less than 5 percent (i.e., less than 5 percent of fetal PbBs will be greater than the target of 10 µg/dL). However, exposure of commercial workers to soils within the RIDEM Soil Removal Area results in a P10 of 10 percent for surface soils and a P10 of 12 percent for surface and subsurface soils combined.

Table 1c presents the modeling results for the construction worker. Exposure of construction workers to sitewide shallow groundwater (incidental ingestion during intrusive activities) results in a P10 of less than 1 percent, which is well below the threshold of 5 percent. However, exposure of construction workers to soils at Quinnville Wellfield, Southern Bank, Nunes Parcel, and RIDEM Soil Removal Area results in P10s of 5 percent, 6 percent, 13 percent, and 89 percent, respectively, which are above the 5 percent threshold.

Table 1d presents the modeling results for the adult recreational user. Exposure of adult recreational users to site-related media associated with Southern Bank, Nunes Parcel, Quinnville Wellfield, Debris Fields, Wetlands, RIDEM Soil Removal Area, and Landfill results in P10s less than 5 percent.

Table 1e presents the modeling results for the older child recreational user. Because this receptor is not of child-bearing age, the ALM was only used to estimate the geometric mean of PbB for the exposed individual. Exposure of older child recreational users to site-related media associated with Southern Bank, Nunes Parcel, Quinnville Wellfield, Debris Fields, Wetlands, RIDEM Soil Removal Area, and Landfill results in PbBs less than 10 µg/dL.

Table 1f presents the modeling results for the adolescent trespasser. Similar to the older child recreational user, the ALM was only used to estimate the geometric mean of PbB for the exposed individual. Exposure of the adolescent trespasser to site-related media associated with Southern Bank, Nunes Parcel, Quinnville Wellfield, Debris Fields, Wetlands, RIDEM Soil Removal Area, and Landfill results in PbBs less than 10 µg/dL.

Table 1g presents the modeling results for the adult angler. Exposure of adult anglers via consumption of fish tissue from the site (OU2) results in a P10 of less 1 percent, which is well below the threshold of 5 percent. Likewise, evaluation of potential lead risks associated with consumption of fish from upstream reaches of the Blackstone River (BR1 and BR2) result in P10s less than 1 percent.

3.4 Uncertainties Associated with the Adult Lead Model

Notable uncertainties associated with the ALM in this evaluation are associated with the limited analytical data for the RIDEM Soil Removal Area and the construction worker soil ingestion rate. At the request of the USEPA, the RIDEM Soil Removal Area was evaluated as a separate subarea within the Nunes Parcel using only three sampling points (SO-033-NP, SO-107-NP, and SO-108-NP). However, this conservatively assumes that the receptor would preferentially spend all of their time in a relatively small area of the site. Lead concentrations in these samples ranged from 10 mg/kg (SO-107-NP) to 5,460 mg/kg (SO-033-NP, 1 to 5 feet).

USEPA guidance (2007) indicates that a soil ingestion rate of 100 mg/day is appropriate for evaluating contact-intensive activities for construction workers. However, at the request of the USEPA, an upper-bound soil ingestion rate of 330 mg/day was used in this evaluation in the ALM. Using a soil ingestion rate of 100 mg/day, the resulting P10s for Quinnville Wellfield and Southern Bank surface soils would be 1 percent and 2 percent, respectively. The P10s for the RIDEM Soil Removal Area and Nunes Parcel (surface and subsurface soil) would be 39 percent

and 3 percent, respectively, if a soil ingestion rate of 100 mg/day was used for the construction worker.

4.0 IEUBK Model for Residential Receptor Populations

The IEUBK Model consists of four modules (exposure, uptake, biokinetics, and variability) that mathematically and statistically link environmental lead exposure to blood lead concentrations for a population of children, ages 0 to 84 months (USEPA, 2002b). USEPA's IEUBK Model (Windows version 1, Build 264) was used to assess risks for the following scenarios for children ages 0 to 84 months:

- Hypothetical future exposure of young child residents to site-wide groundwater
- Current and hypothetical future exposure of young child anglers to fish from the site (OU2) and upstream reaches of the Blackstone River (BR1 and BR2)
- Hypothetical future exposure of young child residents to soils at Nunes Parcel and site-wide groundwater
- Hypothetical future exposure of young child residents to soils at the RIDEM Soil Removal Area and site-wide groundwater.

The application of the IEUBK Model assumed one child, one location, and homogeneous media concentrations. Similar to the ALM, the EPC(s) used in the IEUBK Model represent arithmetic means of the available data. Per the USEPA's request, one-half the laboratory detection limit was used for non-detects in the calculation of arithmetic means.

4.1 IEUBK Model Parameters Values

Tables 2a, 3a, and 5a present the parameter values used in the IEUBK Model. The majority of the parameter values used in the IEUBK Model were defaults, with the exception of using more recent estimates of dietary lead intake, evaluating an alternate diet intake scenario (i.e., fish ingestion), using site-specific lead concentration in drinking water, and using a site-specific background lead concentration for soils. The use of site-specific background soils data was previously approved by the USEPA following the February 20, 2007 meeting in Boston. Specifically, as noted in Table 1: "Technical items discussed during the 2/20/07 meeting in Boston, MA regarding the Peterson Puritan Superfund Site HHRA," on the issue of "identification of background soil samples," Metcalf & Eddy state "offsite soil samples from Mackland Farms will be used as site-specific background samples." Attachment B presents the sample groupings used to calculate site-specific EPCs for each exposure scenario evaluated using the IEUBK Model.

Dietary Data

The default dietary lead intakes in the IEUBK Model are based on data collected by the U.S. Food and Drug Administration (USFDA) in the late 1980s. More recent USFDA (2001) data are available, and therefore, were incorporated into the model. In addition, for the fish consumption scenario, alternate diet intakes consisted of site-specific data for fish tissue collected from OU2, BR1, and BR2. The lead intake from fish was calculated using the following equation:

$$\text{Fish Intake } (\mu\text{g lead/day}) = (\text{Total meat intake rate, g/day}) \times (\% \text{ Total Meat Intake from Fish}) \times (\% \text{ Fish from Source}) \times (\text{Fish Concentration, } \mu\text{g lead/day})$$

Where:

% of Total Meat Intake from Fish = 10%

% Fish Consumption from Source = 100%

The fish concentrations represent the arithmetic means of the fish fillet data for each subarea (OU2 = 0.012 mg/kg; BR1 = 0.013 mg/kg; and BR2 = 0.0056 mg/kg). The resulting lead intakes attributable to consumption of fish for OU2, BR1, and BR2 are presented in Table 4.

Lead Concentration in Drinking Water

To evaluate hypothetical future exposure of residential young children to lead in drinking water, the arithmetic mean of the site-wide groundwater data (2.17 micrograms per liter) was used in the IEUBK Model. This evaluation assumes that site-related groundwater may be used as a potable source in the future, and that current measured concentrations are representative of future concentrations.

Lead Concentration in Soil/Dust

For the site-wide groundwater and fish scenarios, the soil/dust concentration represents a site-specific background concentration (i.e., the arithmetic mean of the Mackland Farms soils data [samples SO-072-MF, SO-073-MF, and SO-074-MF]). For the evaluation of hypothetical future residential young children exposed to soils and groundwater at Nunes Parcel, the soil/dust lead concentration (270 mg/kg) represents the arithmetic mean of surface and subsurface soils from Nunes Parcel. For the evaluation of hypothetical future residential young children exposed to soils and groundwater at the RIDEM Soils Removal Area, the soil/dust lead concentration (2,050 mg/kg) represents the arithmetic mean of surface and subsurface soils (i.e., the three sampling points identified by the USEPA [SO-033-NP, SO-107-NP, and SO-108-NP]).

4.2 IEUBK Model Results

Table 2b presents the input parameters and results for evaluation of hypothetical future exposure of young child residents to site-wide groundwater. There is less than a 1 percent probability that children exposed to lead in groundwater will have a PbB that exceeds the target PbB of concern (10 µg/dL) (i.e., well below the P10 = 5 percent threshold).

Table 3b presents the input parameters and results for evaluation of exposure of young child anglers to fish tissue from OU2. There is less than a 1 percent probability that children exposed to lead in fish will have a PbB greater than 10 µg/dL.

To place OU2 lead risks into perspective, consumption of fish from upstream reaches of the Blackstone River (BR1 and BR2) was also evaluated. Table 3c presents the input parameters and results for evaluation of exposure of young child anglers to fish tissue from BR1. Results indicate there is less than a 1 percent probability that children exposed to lead in fish from BR1 will have a PbB greater than 10 µg/dL. Table 3d presents the input parameters and results for evaluation of exposure of young child anglers to fish tissue from BR2. Results indicate there is less than a 1 percent probability that children exposed to lead in fish from BR2 will have a PbB greater than 10 µg/dL.

Table 5b presents the input parameters and results for evaluation of exposure of hypothetical young child residents to soil and groundwater from Nunes Parcel. Results indicate there is a 2

percent probability (less than the 5 percent threshold) that children exposed to soil and groundwater will have a PbB greater than 10 µg/dL.

Table 5c presents the input parameters and results for evaluation of exposure of hypothetical young child residents to soil and groundwater from the RIDEM Soil Removal Area. Results indicate there is an 87 percent probability (above the 5 percent threshold) that children exposed to soil and groundwater will have a PbB greater than 10 µg/dL.

4.3 Uncertainties Associated with the IEUBK Model

The notable uncertainty associated with the use of the IEUBK Model is that many of the default parameters may not accurately reflect site conditions (e.g., air emissions, dietary lead intake, bioavailability). Specifically, the bioavailability factors used in the model are based on the absolute bioavailability of soluble lead acetate (50 percent) (used for lead in food and water) and the relative bioavailability of lead in soil (60 percent), which yields an absolute bioavailability for soil lead of 30 percent (i.e., 60 percent x 50 percent = 30 percent). The USEPA (1999) notes that the default estimates of bioavailability have significant variability and uncertainty due to many factors related to the site-specific conditions (e.g., lead speciation, mineralogy, soil particle size) and receptor population (complex biological process of gastrointestinal absorption).

5.0 Summary and Conclusions

In summary, the lead evaluation identified the following scenarios as having estimated (potential) lead risks above the USEPA target:

- Exposure of commercial workers to soils within the RIDEM Soil Removal Area
- Exposure of construction workers to soils at Quinnville Wellfield, Southern Bank, Nunes Parcel, and RIDEM Soil Removal Area
- Exposure of hypothetical young child residents to soil and groundwater from the RIDEM Soil Removal Area

However, the quantification of potential risks for the commercial worker, construction worker, and hypothetical young child resident exposed to soils within the RIDEM Soil Removal Area is based on a very limited ($n = 5$) sample size, which may present an artificially high average due to lead concentrations in sample SO-033-NP (2,380 mg/kg in the 0 to 1 foot interval and 5,460 mg/kg in the 1 to 5-foot interval). Although the potential exposure of construction workers to site soils produces risks above the USEPA target, these risks would likely be mitigated with the use of proper health and safety protocols, properly trained personnel, and personal protective equipment.

Table 1a. Summary of Parameter Values Used in the Adult Lead Model (ALM) for Evaluation of Non-Residential Lead Risks Associated with Site-Related Soil, Sediment, Groundwater, and Fish Baseline Human Health Risk Assessment
Peterson Puritan (OU2), Cumberland and Lincoln, Rhode Island

Exposure Variable	Description	Units	Receptor Scenarios					
			Commercial Worker ^[1]	Construction Worker ^[1]	Adult Recreational User ^[2]	Older Child Recreational User ^[2,3]	Adolescent Trespasser ^[2,4]	Adult Angler ^[1]
			Table 1b	Table 1c	Table 1d	Table 1e	Table 1f	Table 1g
PbS	Lead concentration in medium of interest	ppm	Site-specific	Site-specific	Site-specific	Site-specific	Site-specific	Site-specific
R _{fetal/maternal}	Fetal/maternal PbB ratio	--	0.9 [a]	0.9 [a]	0.9 [a]	1.0 [b]	1.0 [b]	0.9 [a]
BKSF _s	Biokinetic Slope Factor (soil, sediment, and food)	µg/dL per µg/day	0.4 [a]	0.4 [a]	0.4 [a]	0.4 [a]	0.4 [a]	0.4 [a]
BKSF _w	Biokinetic Slope Factor (groundwater)	µg/dL per µg/day	NA	0.4 [a]	NA	NA	NA	NA
GSD _i	Geometric standard deviation PbB	--	2.01 [c]	2.01 [c]	2.01 [c]	2.01 [c]	2.01 [c]	2.01 [c]
PbB ₀	Baseline PbB	µg/dL	1.9 [c]	1.9 [c]	1.9 [c]	1.9 [c]	1.9 [c]	1.9 [c]
IR _s	Soil/sediment ingestion rate (including soil-derived indoor dust)	g/day	0.05 [d]	0.33 [o]	0.05 [d]	0.05 [d]	0.05 [d]	NA
IR _f	Food ingestion rate (fish)	g/day	NA	NA	NA	NA	NA	8.9 [e]
IR _w	Shallow groundwater ingestion rate	L/day	NA	0.05 [m]	NA	NA	NA	NA
AF _{s, d, w}	Absorption fraction, Pb in soil, dust, sediment, and groundwater	--	0.12 [a]	0.12 [a]	0.12 [a]	0.12 [a]	0.12 [a]	NA
AF _f	Absorption fraction, Pb in food	--	NA	NA	NA	NA	NA	0.12 [f]
EF _{s, d, w}	Exposure frequency, Pb pathway	days/yr	219 [j]	62 [h]	2 [g]	2 [g]	2 [g]	365 [j]
AT _{s, d, w}	Averaging time, Pb pathway	days/yr	365 [k]	84 [l]	7 [n]	7 [n]	7 [n]	365 [k]

Notes:

[1] Lead exposures for these receptors were evaluated individually for each applicable subarea. Consistent with the ALM guidance (USEPA, 2003a; 2007), the arithmetic mean of lead concentrations was used in the ALM.

[2] A time-weighted approach was used to evaluate potential lead risks for these receptors in the ALM, consistent with Example 6 in Appendix A in USEPA (2003b).

[3] Older child = 6 - 12 years of age

[4] Adolescent = 9 - 18 years of age

[5] Consistent with USEPA (2003a; 2004; 2007) guidance, dermal exposures to lead in aqueous and non-aqueous media were not quantitatively evaluated with the ALM due to the uncertainty in assigning a dermal absorption fraction that would apply to the numerous inorganic forms of lead that are typically found in environmental settings.

[a] Default value (USEPA, 2003a).

[b] Fetal/maternal PbB ratio does not apply because receptor is assumed to be an older child (6-12 years) or adolescent (9-18 years); risks to fetus of pregnant women are evaluated in adult receptor scenarios.

[c] Default value for non-Hispanic white populations from the Northeast region (USEPA, 2002).

[d] Default CTE value for soil ingestion (USEPA, 2003a; 2007). Value for commercial worker assumes non-contact-intensive activities.

[e] CTE fish ingestion rate based on the 50th percentile for Maine anglers (Ebert et al., 1993. Estimating Consumption of Freshwater Fish among Maine Anglers. *North American Journal of Fisheries Management* 13:737-745.). Assumes 100% of fish consumed are from on-site sources.

**Table 1a. Summary of Parameter Values Used in the Adult Lead Model (ALM) for Evaluation of Non-Residential Lead Risks Associated with Site-Related Soil, Sediment, Groundwater, and Fish Baseline Human Health Risk Assessment
Peterson Puritan (OU2), Cumberland and Lincoln, Rhode Island**

Notes (continued):

- [f] Value considered protective for bioavailable fraction of lead in fish (USEPA, 2007).
 [g] Reflects the same CTE value used in baseline human health risk assessment (2 days per week for approximately 6 months). Applying the time-weighted approach consistent with note [2] above, the resulting exposure frequency is set equal to 2 days/week.
 [h] Same CTE value used in baseline human health risk assessment (5 days per week for approximately 12 weeks).
 [i] Default central tendency estimate of exposure frequency for commercial/industrial workers from USEPA (2007).
 [j] Fish ingestion rate reflects a longterm average daily intake assuming 100% of fish are obtained from the site; therefore, EF is 365 days/year.
 [k] Averaging time appropriate for chronic exposure scenario (USEPA, 2003a; 2007).
 [l] Averaging time is based on EF to avoid diluting exposures over the entire year (7 days per week x 12 weeks/year = 84 days/year).
 [m] Default surface water contact rate for recreational swimmers (USEPA, 1989). Assumed to provide a conservative estimate of incidental ingestion by construction workers exposed to shallow groundwater.
 [n] Applying the time-weighted approach consistent with note [2] above, the resulting averaging time is set equal to 7 days/week.
 [o] Same CTE value used in baseline human health risk assessment.
 µg/dL = micrograms per deciliter
 g/day = grams per day
 L/day = liters per day
 NA = not applicable

Notes:

ALM Version date 5/19/05

[1] Current scenario, as indicated in Table 1 of the baseline HHRA.

[2] Future scenario, as indicated in Table 1 of the baseline HHRA.

[3] Per USEPA's request, the RIDEM soil removal area was evaluated using only three soil samples, only one of which (SO-033-NP) was surficial (0 - 1 foot below ground surface). Therefore, the surface soil PbS for the soil removal area represents one sampling point rather than an arithmetic mean of several sampling points.

[4] Per USEPA's request, the RIDEM soil removal area was evaluated using only three soil samples.

[a] Per USEPA's request, arithmetic means were calculated using one-half the laboratory detection limit for non-detects.

ALM Version date 5/19/05

[1] Current scenario, as indicated in Table 1 of the baseline HHRA.

[2] Future scenario, as indicated in Table 1 of the baseline HHRA.

[a] Per USEPA's request, arithmetic means were calculated using one-half the laboratory detection limit for non-detects.

Table 2a. Summary of Parameter Values Used in the Integrated Exposure Uptake Biokinetic (IEUBK)
Model for Evaluation of Residential Lead Risks Associated with Site-Related Groundwater
Baseline Human Health Risk Assessment
Peterson Puritan Site (OU2), Cumberland and Lincoln, Rhode Island

Receptor Scenario: Young Child ^[1,2] (Resident)

Parameter	Value	Units
Indoor air lead concentration (% of outdoor)	30 [a]	%
AIR (by year)		
Air Concentration		
Age (years) = 0 - 1	0.10 [a]	µg/m ³
1 - 2	0.10 [a]	µg/m ³
2 - 3	0.10 [a]	µg/m ³
3 - 4	0.10 [a]	µg/m ³
4 - 5	0.10 [a]	µg/m ³
5 - 6	0.10 [a]	µg/m ³
6 - 7	0.10 [a]	µg/m ³
Time Outdoors		
Age (years) = 0 - 1	1 [a]	hours/day
1 - 2	2 [a]	hours/day
2 - 3	3 [a]	hours/day
3 - 7	4 [a]	hours/day
Ventilation Rate		
Age (years) = 0 - 1	2 [a]	m ³ /day
1 - 2	3 [a]	m ³ /day
2 - 5	5 [a]	m ³ /day
5 - 7	7 [a]	m ³ /day
Lung Absorption	32 [a]	%
DIET (by year)		
Dietary Lead Intake		
Age (years) = 0 - 1	3.16 [b]	µg Pb/day
1 - 2	2.60 [b]	µg Pb/day
2 - 3	2.87 [b]	µg Pb/day
3 - 4	2.74 [b]	µg Pb/day
4 - 5	2.61 [b]	µg Pb/day
5 - 6	2.74 [b]	µg Pb/day
6 - 7	2.99 [b]	µg Pb/day
ALTERNATE DIET SOURCES (by food class)		
Concentration:		
home-grown fruits	0 [a]	µg Pb/g
home-grown vegetables	0 [a]	µg Pb/g
fish from fishing	0 [a]	µg Pb/g
game animals from hunting	0 [a]	µg Pb/g

**Table 2a. Summary of Parameter Values Used in the Integrated Exposure Uptake Biokinetic (IEUBK)
Model for Evaluation of Residential Lead Risks Associated with Site-Related Groundwater
Baseline Human Health Risk Assessment
Peterson Puritan Site (OU2), Cumberland and Lincoln, Rhode Island**

Receptor Scenario: Young Child ^[1,2] (Resident)

Parameter	Value	Units
ALTERNATE DIET SOURCES (by food class) (continued)		
Percent of food class:		
home-grown fruits	0 [a]	%
home-grown vegetables	0 [a]	%
fish from fishing	0 [a]	%
game animals from hunting	0 [a]	%
DRINKING WATER		
Lead Concentration in drinking water	2.17 [c]	µg/L
Ingestion rate:		
Age (years) = 0 - 1	0.20 [a]	L/day
1 - 2	0.50 [a]	L/day
2 - 3	0.52 [a]	L/day
3 - 4	0.53 [a]	L/day
4 - 5	0.55 [a]	L/day
5 - 6	0.58 [a]	L/day
6 - 7	0.59 [a]	L/day
SOIL/DUST INGESTION		
Concentration:		
soil	101.2 [d]	µg/g
dust	101.2 [d]	µg/g
Soil/dust ingestion weighting factor (% soil)	45 [a]	%
Soil/dust ingestion:		
Age (years) = 0 - 1	0.085 [a]	g/day
1 - 4	0.135 [a]	g/day
4 - 5	0.100 [a]	g/day
5 - 6	0.090 [a]	g/day
6 - 7	0.085 [a]	g/day
SOIL/DUST MULTIPLE SOURCE ANALYSIS		
Fraction of indoor dust lead attributable to soil	0.70 [a]	unitless
Ratio of dust lead concentration to outdoor air lead concentration	100 [a]	µg Pb/g dust per µg Pb/m ³ air
BIOAVAILABILITY FOR GUT ABSORPTION PATHWAYS		
Total lead absorption (at low intake):		
diet	50 [a]	%
drinking water	50 [a]	%
soil	30 [a]	%
dust	30 [a]	%
alternate source	0 [a]	%
Fraction of total net absorption at low intake rate that is attributable to non-saturable (passive) processes	0.2 [a]	unitless

**Table 2a. Summary of Parameter Values Used in the Integrated Exposure Uptake Biokinetic (IEUBK)
Model for Evaluation of Residential Lead Risks Associated with Site-Related Groundwater
Baseline Human Health Risk Assessment
Peterson Puritan Site (OU2), Cumberland and Lincoln, Rhode Island**

Receptor Scenario: Young Child ^[1,2] (Resident)

Parameter	Value	Units
ALTERNATE SOURCES OF LEAD		
Total lead intake:		
Age (years) = 0 - 1	0 [a]	µg/day
1 - 2	0 [a]	µg/day
2 - 3	0 [a]	µg/day
3 - 4	0 [a]	µg/day
4 - 5	0 [a]	µg/day
5 - 6	0 [a]	µg/day
6 - 7	0 [a]	µg/day
MATERNAL-TO-NEWBORN LEAD EXPOSURE		
Mothers blood lead concentration at childbirth	2.5 [a]	µg/dL
PLOTING AND RISK ESTIMATION		
Geometric standard deviation (GSD) for blood lead	1.6 [a]	unitless
Blood lead level of concern	10 [a]	µg/dL
COMPUTATION OPTIONS		
Iteration time step for numerical integration	4 [a]	hours

Notes:

- [1] Young child = 0 - 7 years of age (0 - 84 months)
- [2] Assumes exposure to site-specific groundwater concentrations of lead via ingestion from a potable source
- [3] The IEUBK model (USEPA, 2002) does not allow for a quantitative evaluation of dermal exposures to lead in groundwater presumably due to the uncertainty in assigning a dermal absorption fraction that would apply to the numerous inorganic forms of lead that are typically found in environmental settings.
- [a] Default value (USEPA, 2002).
- [b] Defaults in IEUBK model represent U.S. Food and Drug Administration (FDA) data collected in the late 1980s. More recent FDA (2001) data are presented. Source: FDA (2001) Total Diet Study. U. S. Food and Drug Administration Center for Food Safety and Applied Nutrition Office of Plant and Dairy Foods and Beverages. June 2001. Available online at The U.S. Food and Drug Administration Center for Food Safety and Applied Nutrition Web site. (<http://www.cfsan.fda.gov/~comm/tdstoc.html>).
- [c] Groundwater concentration represents arithmetic mean of site data.
- [d] Background soil concentrations of lead represent arithmetic mean of Mackland Farms soils data (samples)

5 - 6	0.062 [h]	µg Pb/day
6 - 7	0.068 [h]	µg Pb/day

Notes:

[1] Young child = 0 - 7 years of age (0 - 84 months)

[2] Assumes exposure to lead concentrations via consumption of edible fish tissue.

[a] USEPA. Frequently Asked Questions - Can IEUBK be Used to Develop a Site-specific Fish Advisory?

<http://www.epa.gov/superfund/lead/ieubkfaq.htm#fish>

[b] Estimate for recreational anglers. USEPA. Frequently Asked Question - Can IEUBK be Used to Develop a

Site-specific Fish Advisory? <http://www.epa.gov/superfund/lead/ieubkfaq.htm#fish>

[c] Assumes 100% of fish come from Blackstone River or on-site ponds. This may overestimate lead intake

from fish because a portion of the default dietary Pb intake includes fish from other sources.

[d] Fish tissue concentration represents arithmetic mean of site-related data.

OU2 fish = 0.012 mg/kg; BR1 fish = 0.013 mg/kg; BR2 fish = 0.0056 mg/kg

[e] Intake from Fish (µg Pb/day) = (Total Meat Intake Rate g/day) x (% Total Meat Intake from Fish) x (%

from Source) x (Concentration in Fish µg Pb/g)

[f] Arithmetic mean of OU2 fish fillets is 0.012 mg/kg.

[g] Arithmetic mean of BR1 fish fillets is 0.013 mg/kg.

[h] Arithmetic mean of BR2 fish fillets is 0.0056 mg/kg.

Notes:

[1] Young child = 0 - 7 years of age (0 - 84 months)

[2] Assumes exposure to lead in onsite surface and subsurface soils within Nunes Parcel and ingestion of site-related groundwater.

[3] The IEUBK model (USEPA, 2002) does not allow for a quantitative evaluation of dermal exposures to lead in soils presumably due to the uncertainty in assigning a dermal absorption fraction that would apply to the numerous inorganic forms of lead that are typically found in environmental settings.

[a] Default value (USEPA, 2002a).

[b] Defaults in IEUBK model represent U.S. Food and Drug Administration (FDA) data collected in the late 1980s. More recent FDA (2001) data are presented. Source: FDA (2001) Total Diet Study. U. S. Food and Drug Administration Center for Food Safety and Applied Nutrition Office of Plant and Dairy Foods and Beverages. June 2001. Available online at The U.S. Food and Drug Administration Center for Food Safety and Applied Nutrition Web site. (<http://www.cfsan.fda.gov/~comm/tdstoc.html>).

[c] Groundwater concentration represents arithmetic mean of site data.

[d] Soil concentration represents arithmetic mean of site data.
