VOLUME III

EXECUTIVE SUMMARY

This document presents the Baseline Human Health and Ecological Risk Assessment for the Southwest Properties Site in Woburn, Massachusetts (the Site). The Site is primarily comprised of three contiguous parcels of land known as Aberjona Auto Parts (Aberjona property), Whitney Barrel (Whitney property), and Murphy's Waste Oil (Murphy property.

The Site is part of the 2nd operable unit (OU-2) of the Wells G&H Superfund Site. The purpose of this report was to assess contamination at the Site and evaluate human health and ecological risks related to the contamination. The environmental setting, geology, surface hydrology, hydrogeology, nature and extent of contamination, fate and transport of contaminants, human health risk and ecological risk are summarized in the following text.

The Site is part of the Well G&H Superfund Site, which is comprised of approximately 330 acres bounded by Route 128/Interstate 95 to the north, the Boston and Main (B&M) Railroad to the west, Interstate 93 to the east and Salem and Cedar Streets to the south. The Site is situated within the southwestern corner of the Wells G&H Superfund Site, and primarily comprised of three parcels of land known as Aberjona Auto Parts (Aberjona property, 6.5 acres), Whitney Barrel (Whitney property, 2.7 acres), and Murphy Waste Oil (Murphy property, 3.6 acres), which are also listed as three separate MADEP BWSC "Chapter 21-E" sites. The Site is approximately 13 acres.

The Site is approximately rectangular with its long axis oriented approximately northeast southwest along Salem Street. The Aberjona River flows north to south along the eastern boundary of the Site adjacent to the Aberjona property. The B&M railroad abuts the Site (at the Murphy property) to the west and Salem Street to the south along which each property has frontage. Three industrially zoned properties with wood framed structures that appear to be former residences are also next to the Murphy property to the southwest of the Site. The Wildwood Conservation Corporation property (Wildwood property), which is one of five source area properties associated with Operable Unit 1 of the Wells G&H Superfund Site, lies on the adjacent parcel to the north of all three properties (Aberjona, Whitney and Murphy properties).

The land use at and in vicinity of the Site is highly developed with light commercial and light industrial parks bordering the wetlands area associated with the Aberjona River floodplain. Portions of each of the properties are located within the mapped 100-year floodplain. The Southwest Properties current land uses are commercial/industrial at all three properties, with an existing residence located on the Aberjona property. The Southwest Properties are zoned industrial (Industrial Park, I-P) (City of Woburn, 2012). Currently, the Aberjona property is comprised of auto repair/storage operations and a dog exercise area enclosed within a locked fence, an existing single family residence, and an enclosed ice skating rink. The commercial buildings at the Aberjona property are currently utilized by automotive repair operations, a private athletic training center, a canine daycare facility, and a landscaper. The Whitney property is utilized by a variety of small businesses (e.g., construction, landscaping, automotive repair, and an automotive glass repair company). The Murphy property is leased by Clean Harbors Environmental Services, Incorporated (CHES), and is a registered Treatment, Storage, and Disposal Facility (TSDF) under the Resource Conservation and Recovery Act (RCRA), currently used for treatment and storage of waste oil. In the recent past, the Aberjona, Whitney and Murphy properties have served as an automobile salvage yard/service station, a barrel washing facility, and a waste oil reclamation facility, respectively. A wetland area lies between the upland portions of the Murphy, Whitney, Wildwood and Aberjona properties, and is referred to throughout this report as the Murphy Wetland. Figure ES-1 presents a plan of the Southwest Properties and shows the medium-specific exposure points evaluated in the risk assessment.

Data used to prepare this risk assessment were obtained from several different investigations, and include data from 2010/2011/2013 soil, subslab soil gas, indoor air and groundwater investigations. Table ES-1 summarizes the investigative work used to prepare the human health and ecological risk assessments. Monitoring wells BSW-2, BW-2R, BOW-16, BSSW-16, BW-16R, and the S77 well cluster are located on the Wildwood property. Due to their close proximity to the Southwest Properties, the chemical data for groundwater obtained from them have been included in the risk assessment. Soil and groundwater data were used as inputs to transport and dilution/dispersion models in order to estimate outdoor trench air concentrations for the human health risk assessment. This transport and dilution/dispersion model used

property-specific information on depth to groundwater as well as appropriate values for soil properties to establish reasonably conservative site-specific modeled outdoor trench air exposure point concentrations. The vapor intrusion pathway[1] was qualitatively evaluated at the commercial buildings since the building at Whitney is not currently occupied, and only sporadic, low-to-moderate level detections of volatile organic compounds (VOCs) were seen in soil gas beneath the commercial buildings at the Aberjona and Murphy properties. The vapor intrusion pathway was quantitatively evaluated at the occupied existing Aberjona residence using two seasonal rounds of subslab soil gas and indoor air data.

Numerous Chemicals of Potential Concern (COPCs) were detected in Site media. In soil, COPCs generally consisted of the following classes of compounds: chlorinated VOCs, polyaromatic hydrocarbons (PAHs), pesticides, metals, polychlorinated biphenyls (PCBs), and dioxin-like PCB congeners, as well as aromatic and aliphatic petroleum hydrocarbons. In groundwater, the COPC classes included chlorinated and non-chlorinated VOCs, semi-volatile organic compounds (SVOCs) (including PAHs), aromatic and aliphatic petroleum hydrocarbons, metals, PCBs and dioxin-like PCB congeners, and pesticides. In outdoor trench air, COPCs were limited to trichloroethene. COPCs in sediment included chlorinated and non-chlorinated VOCs, PAHs, aromatic and aliphatic petroleum hydrocarbons, metals (including hexavalent chromium), PCBs, dioxin-like PCB congeners and pesticides. In surface water, COPCs were limited to inorganics (e.g., chromium, cobalt, cyanide, iron and manganese). Indoor air COPCs at the existing Aberjona residence included chloroform and trichloroethene.

Human Health Risk Assessment Summary. Potential non-carcinogenic and carcinogenic human health risks were quantitatively assessed for the central tendency exposure (CTE) and reasonable maximum exposure (RME) cases for surface soil, subsurface soil, groundwater, outdoor trench air, surface water, sediment and indoor air at each exposure point determined to be accessible to human receptors currently or in the future.

[1] Vapor intrusion is defined as the movement of VOCs from groundwater into soil gas and then into a building. Only VOCs present in indoor air as part of a complete vapor intrusion pathway are evaluated in the risk assessment.

The arsenic bioavailability study that was performed as part of the Baseline Human Health and Ecological Risk Assessment Report, Wells G&H Superfund Site, Aberjona River Study, Operable Unit 3 (Aberjona River Study Baseline Risk Assessment) (EPA, 2004) was also used in this risk assessment. This study was also referenced in the Draft Final MSGRP Remedial Investigation Report, Industri-Plex Superfund Site, Operable Unit 2, Woburn, Massachusetts (EPA, 2005; Appendix 6). The bioavailability study was completed to assist in the quantification of sediment risks. This site-specific bioassay determined that arsenic is absorbed less efficiently from sediment than from a water medium. The most conservative relative bioavailability estimate determined in the study was used to quantify sediment ingestion risks at the Southwest Properties.

Site-specific hexavalent chromium data were collected and used in the risk assessment to more accurately characterize soil, groundwater, and sediment risks at the Southwest Properties. Only hexavalent chromium data obtained using the ion chromatography method for soil/sediment and Method 7196A for groundwater were quantitatively evaluated in the human health risk assessment.

EPA recommends calculation of the 95-percent upper confidence limit (95% UCL) on the arithmetic mean concentration for the estimation of both the RME and CTE risk (EPA, 1989; 1992) for most scenarios. Therefore, whenever possible, the 95% UCL has been calculated and used as the EPC for both the RME and CTE cases. When the 95% UCL was greater than the maximum detected value, the maximum and average concentrations were generally used. The 95% UCLs were calculated using EPA's program ProUCL Statistical Software (EPA, 2011; 2013). The 95% UCL values were calculated by this program when a sufficient number of samples were available from an exposure point. When too few samples were available, the program was unable to calculate a reliable 95% UCL value.

Possible human exposure to the selected COPCs was characterized through exposure pathways for current and future land use. An exposure pathway describes the course a chemical follows while moving through environmental media to a receptor. An exposure pathway may consist of a mechanism of release of contaminants to an environmental medium (e.g., soil), an exposure

route (e.g., ingestion) and a receptor (e.g., trespasser). An exposure pathway is considered complete when contact by a receptor with contaminated media may occur currently or in the future. For purposes of this risk assessment, only potentially complete exposure pathways were quantitatively evaluated.

Current land use is commercial/industrial at all three sites, except for the occupied existing residence at the Aberjona property. Sediment and floodplain soil impacts in the backyard of the existing residence at the Aberjona property were previously evaluated as part of the Aberjona River Study Baseline Risk Assessment (EPA, 2004 and Appendix 6 of EPA, 2005). The Southwest Properties are zoned industrial (Industrial Park, I-P) (City of Woburn, 2012). Many of the on-site areas of known contamination are currently fenced or covered with pavement or structures. However, access is not limited for a portion of the Whitney property (only the building space is secured in parts). In addition, commercial workers may access the secured areas. Based on this information, current receptors include commercial workers at all three properties, trespassers at the Whitney property, and residents potentially exposed to vapor intrusion pathway VOCs in indoor air at the existing Aberjona residence. Future receptors for all three properties include commercial workers, trespasser, recreational users and construction workers, including exposures to shallow groundwater encountered during excavation activities at each property. In addition, the future Aberjona resident is evaluated for potential exposures to vapor intrusion pathway VOCs in indoor air.

MassDEP prepared a Groundwater Use and Value Determination (MassDEP, 2004; EPA, 2004 and 2005) for the Wells G&H Superfund Site in accordance with 1998 Memorandum of Agreement between EPA and MassDEP. MassDEP concluded a “medium” groundwater use and value determination was appropriate for the Wells G&H aquifer because of its significant current and future ecological value to the Aberjona River and associated wetlands and its potential human value as a drinking water supply in the future. Based upon this determination, a future residence is also evaluated for exposure to groundwater to address the potential for future potable use of contaminated groundwater originating from the Southwest Properties.

A summary of the exposure points evaluated in the risk assessment is provided below by scenario and shown on Figure ES-1.

Exposure Point	Current Scenario	Future Scenario
Aberjona Soil	X	X
Whitney Soil	X	X
Murphy Soil	X	X
Murphy Wetland Sediment/Surface Water	X	X
Existing Aberjona Residence Indoor Air	X	X
Site Groundwater*	N/A	X

Notes: N/A – Not applicable X – Included exposure point

*Site Groundwater exposures include site-wide residential tap water usage and property-specific construction worker contact while excavating.

Estimated risks were compared to the EPA target Incremental Lifetime Cancer Risk (ILCR) range of 10^{-6} to 10^{-4} and target hazard index (HI) of 1 for non-carcinogenic effects.

Table ES-2 and Figure ES-2 summarize the results of the estimated cancer and non-cancer risk for the evaluated properties/areas for the major contributors to risk: ILCRs $>10^{-4}$ or HIs >1, or the contributor with the highest cancer risk if no single compound had a cancer risk of $>10^{-4}$. Risks are summarized for both the RME and CTE receptors for each of the evaluated areas. When risks were estimated for a child and adult receptor, the child HIs are presented as the most conservative, while ILCR are the sum of the child and adult risks (i.e., a total receptor cancer risk). The risks presented by property have been summed together, as appropriate, when a receptor would be exposed to more than one medium during site activities. The Murphy Wetland area was evaluated as an additional separate exposure point because it may have been impacted by more than one of the adjacent properties or by other neighboring properties. In cases where the total pathway HI exceeded 1, COPCs having similar systemic effects were summed for each pathway and medium. The following summarizes the scenarios and contaminants that are major contributors to risk (ILCRs $>10^{-4}$ or HIs >1). Other contributors to risk (10^{-4} > ILCRs > 10^{-6} and HIs > 1) are discussed in Sections 3.0 and 5.0 of this report.

Lead in soil and sediment was evaluated through the use of EPA models for children and adults. The lead evaluation indicated that exposures to lead in current and future soil exposure scenarios would not result in adult or childhood blood lead levels in excess of blood lead level goals. Therefore, lead in soil was determined not to be of concern for human receptors at the Southwest

Properties. Lead in groundwater was evaluated by comparing monitoring well concentrations to the Safe Drinking Water Act (SDWA) action level of 15 micrograms per liter (µg/L).

Aberjona Property. The ILCRs and HIs are all below risk management criteria for all scenarios evaluated.

Whitney Property[2]**.** The RME and/or CTE ILCR and HI exceed the target risk range for the Future Adult/Child Recreational User and Future Construction Worker. The major risk contributors for the Adult/Child Recreational User are direct contact with benzo(a)pyrene and total PCBs in surface soil, and direct contact with heptachlor, total PCBs and dioxin-like PCB congeners (expressed in PCB toxicity equivalents [TEQ]) in subsurface soil. The major risk contributors for the Construction Worker are direct contact with total PCBs and PCB TEQ in subsurface soil, and direct contact with cis-1,2-dichloroethene, tetrachloroethene and trichloroethene in shallow groundwater.

Murphy Property. The RME HI exceeds the target risk range for the Future Adult/Child Recreational User. The major risk contributors for the Adult/Child Recreational User is direct contact with thallium in surface and subsurface soil. In addition, the RME HI exceeds the target risk range for the Future Construction Worker. The major risk contributors for the Construction Worker is direct contact with cis-1,2-dichloroethene in shallow groundwater.

Murphy Wetland. The RME and/or CTE HI exceeds the target risk range for the Future Older Child Trespasser and Future Adult/Child Recreational User. The RME HI was above the target HI of 1 for the Future Older Child Trespasser and RME and CTE HIs were above the target HI of 1 the Future Young Child/Adult Recreational User. The major risk contributor for the Future Trespasser is direct contact with total PCBs in sediment. The major risk contributors for the

[2] Worker protective measures should be used if excavation work is performed prior to remedy implementation near the rear of the building in the vicinity of the drain line connecting the former Whitney drum storage area to the municipal sewer system. During test pit excavation activities in this area in 2011, odors were observed and excavation workers were outfitted with half-faced respirators with organic vapor cartridges due to elevated VOC readings.

Future Recreational receptor are direct contact with total PCBs and C11-C22 aromatics in sediment for the RME case and total PCBs for the CTE case. The lead evaluation for sediment indicated that future young child recreational exposures could result in childhood blood lead levels in excess of blood lead level goals. The highest lead concentrations in sediment are located at sampling locations SW-2 (35,100 milligrams per kilogram [mg/kg]), P-12 (24,900 mg/kg), P-14 (16,800 mg/kg), MR-11 (12,000 mg/kg) and P-43 (11,100 mg/kg).

Indoor Air at Existing Aberjona Residence. ILCRs are within or below the target risk range of 10^{-6} to 10^{-4} and target organ HIs are less than 1 for current and future potential exposures to vapor intrusion pathway VOCs in indoor air at the existing Aberjona residence.

TCE, PCE and chloroform were not found at significant concentrations for resident exposure in any indoor air samples. However, subslab soil gas concentrations of these compounds are greater than EPA soil gas screening levels for residential properties, with the subslab soil gas concentrations of TCE being the most elevated. The presence of elevated concentrations of VOCs, in particular TCE, in subslab soil gas beneath the existing Aberjona residence indicates a potential for future vapor intrusion to occur if building conditions were to change.

Site-Wide Future Resident Tap Water Use. The RME and CTE cancer and non-cancer risks exceed risk management criteria for the site-wide future resident exposed to groundwater during household use. The major risk contributors associated with RME exceedances are benzene, 1,1-dichloroethane, cis-1,2-dichloroethene, trans-1,2-dichloroethene, 1,4-dioxane, methylene chloride, tetrachloroethene, 1,2,3-trichlorobenzene, 1,2,4-trichlorobenzene, 1,1,2-trichloroethane, trichloroethene, vinyl chloride, xylenes (total), C5-C8 aliphatics, C9-C12 aliphatics, C9-C10 aromatics, C9-C18 aliphatics, C11-C22 aromatics, 2-methylnaphthalene, naphthalene, PCB TEQ, total PCBs, aldrin, alpha-BHC, lindane, heptachlor, heptachlor epoxide, arsenic, cobalt, iron, and manganese. In the CTE case, cis-1,2-dichloroethene, 1,2,4-trichlorobenzene, 1,1,2-trichloroethane, trichloroethene, vinyl chloride, C9-C12 aliphatics, C9-C18 aliphatics, naphthalene, total PCBs, arsenic, and manganese were the major risk contributors. In addition, the maximum concentration of lead detected in groundwater (129 µg/L) exceeds the SDWA action level. The elevated lead levels in Murphy Wetland sediment may be related to shallow

groundwater concentrations in the vicinity of monitoring wells MW-24, MW-16 and MW-18S which displayed groundwater lead concentrations of 129 µg/L, 36.2 µg/L and 16.8 µg/L, respectively. These monitoring wells are located within or adjacent to the Murphy Wetland.

Should a change in land use at the Southwest Properties be contemplated that would include activities and uses not evaluated in the risk assessment, further evaluation will be required to assess the risks associated with the proposed land use change, including use of groundwater for purposes not identified in the risk assessment. In addition, the future vapor intrusion pathway will require further evaluation if a change in usage of any of the existing commercial buildings is contemplated that would result in higher occupancy (e.g., full-time commercial use of the Whitney or Murphy buildings or daycare use of the Aberjona building), or as part of new building construction including any addition to existing buildings on any of the properties. Use of a vapor barrier or subslab system may be appropriate to mitigate the vapor intrusion pathway in instances of future development/construction of occupied buildings.

Ecological Risk Assessment

The effects-based screening resulted in the selection of four contaminants of potential ecological concern (COPECs) in surface water (all inorganics), 53 COPECs in sediment (5 volatile organic compounds [VOCs], 21 semi-volatile organic compounds [SVOCs], 7 pesticides/PCBs and 20 inorganics) and 11 COPECs in surface soil (2 PCB Aroclors and 9 inorganics) for evaluation in the Ecological Risk Assessment (ERA). Five indicator species or indicator communities were selected to evaluate risks associated with exposure to the COPECs in the surface water and sediment/surface soil of the Site. Endpoints in the ERA were selected to represent ecological attributes that are to be protected (assessment endpoints) and a measurable characteristic of those attributes (measurement endpoints) that can be used to gauge the degree of impact that has or may occur.

Each endpoint has associated with it a magnitude of risk and a degree of uncertainty. The magnitude of risk incorporates both the degree to which the endpoint was exceeded and also the proportion of the habitat affected. If the No Observable Adverse Effect Level (NOAEL) toxicity

reference value (TRV) or the lower effects threshold (i.e., chronic Ambient Water Quality Criteria [AWQC], Threshold Effect Concentration [TEC], or Lowest Effect Level [LEL]) was exceeded at the Site, the contaminant was concluded to pose a low risk to populations. The highest risk was associated with contaminants that exceeded upper threshold effects levels (i.e., acute AWQC, Probable Effect Concentration [PEC] or – Severe Effect Level [SEL], Lowest Observed Adverse Effect Level [LOAEL] TRVs). If high hazard quotients (HQs) were present only for the maximum (or 95% UCL) COPEC concentration, the magnitude of the overall risk to the population from exposure to the COPEC was considered low.

Figure ES-3 summarizes the results of the ecological risk assessment for each of the assessment endpoints showing a high risk potential within the Murphy Wetland. Based on the analysis of the five selected indicators/endpoints in the ERA, there were no indications of significant ecological risk associated with VOC, SVOC and pesticide contamination within the Murphy Wetland. However, the ERA suggests that PCBs (both Aroclors and dioxin-like congeners) may pose current and future risks to the mammalian indicator populations of herbivores and/or insectivores as represented by the muskrat and short-tailed shrew, respectively. In addition, chromium may also pose risk to mammalian herbivores and insectivores foraging within the seasonally ponded area and mammalian insectivores foraging within the forested/scrub-shrub wetland. Risks to avian omnivores as represented by the mallard are expected to be low.

Analysis of the mean exposure assessment for muskrat indicated HQs greater than 1 based on LOAEL TRVs, for high molecular weight (HMW) polyaromatic hydrocarbons (PAHs), PCB Aroclors 1254 and 1260, dioxin-like PCB congeners, antimony, chromium, and lead. The mean estimated exposure to antimony and lead does not exceed the upper effect level based on the Lowest Observed Adverse Effect Level (LOAEL) TRV. However, mean exposure doses of PCB Aroclors 1254 and 1260, dioxin-like PCB congeners (exhibiting dioxin-like toxicity), and chromium estimated to be ingested by the muskrat result in HQs above 1 based on LOAEL TRVs. Due to the elevated HQs (particularly for PCB Aroclor 1254), the magnitude of the risk for muskrat exposure to these COPECs is high. These results indicate a potential impact on reproduction of mammal populations such as muskrat exposed to PCBs in the diet while foraging in the seasonally ponded area of the Murphy Wetland.

The mallard was used to represent waterfowl having relatively high exposure to sediments. Based on NOAEL TRVs, lead represented the only COPEC to have a HQ greater than 1 for the Site based on the average exposure case. The concentrations of lead indicated low risk for reduction in reproduction or sublethal effects to populations, but there was no evidence for high risk to populations since the lead LOAEL HQ was less than 1. The assessment of the waterfowl endpoint indicates a low risk to the sub-population of mallards at the seasonally ponded area of the Murphy Wetland from exposure to lead. The magnitude of the risk to mallard populations from lead was low since it is based on the NOAEL TRV value, which represents the threshold for effects for potential impacts to populations.

Short-tailed shrew exposure models were used to evaluate potential risk to small mammal populations living in and near the Murphy Wetland. Analysis of the mean exposure assessment for shrew indicated HQs greater than 1, based on LOAEL TRVs, for HMW PAHs, PCB Aroclors 1254 and 1260 and dioxin-like PCB congeners, antimony, chromium and lead at the seasonally ponded area of the Murphy Wetland while PCB Aroclor 1254, chromium and lead have HQs greater than 1 (also based on LOAEL TRV) at the forested/scrub-shrub area of the Murphy Wetland. However, the mean exposure doses of dioxin-like PCB congeners, PCB Aroclor 1254 and 1260 and chromium estimated to be received by the shrew at the seasonally ponded area and PCB Aroclors 1254 and 1260 and chromium at the forested/scrub-shrub areas result in an HQ at or above 1 based on their LOAEL TRVs. Due to the elevated HQs (particularly for dioxin-like PCB congeners exhibiting dioxin-like toxicity), the magnitude of the risk for shrew exposure to PCBs is high. These results indicate a potential impact on reproduction of mammal insectivore populations such as shrews exposed to PCBs in their diet while foraging in the seasonally ponded and forested/ scrub-shrub areas of the Murphy Wetland.

The benthic invertebrate endpoints suggest that there may be impacts from total PCBs and inorganic contaminants, especially chromium, lead, and zinc with the highest HQs attributable to PCBs, chromium and lead. Since the TRVs used for each of these COPECs were the PECs (probable effect concentrations), they represent contaminant levels that potentially eliminate many of the benthic organisms within the community. Surface water concentrations of cyanide, are of

concern as this COPEC exceeds its chronic water quality criterion, but is less than its acute water quality criterion. Biological effects evaluations, in the form of sediment toxicity testing or benthic community structure were not undertaken for this ERA.

Notes

Bolded values exceed a cancer risk of 1E-04 or a target organ HI of 1.

HI - Hazard Index
RME - Reasonable Maximum Exposure
CTE - Central Tendency Exposure

* Based on childhood lead model for sediment.
\+ Based on exceedance of Safe Drinking Water Act Action Level for groundwater.
(C) - Carcinogenic Risk
(NC) - Noncarcinogenic Risk
NE - Not Evaluated
N/A - Not Applicable

1.0 INTRODUCTION

1.1 Purpose Scope and Organization of the Report

EPA's Remedial Investigation/Feasibility Study (RI/FS) at the Wells G&H Superfund Site Operable Unit 2 (OU-2) (Southwest Properties) in Woburn, Massachusetts (i.e., the Site) (TRC Environmental Corporation (TRC) received Contract Number GS-10F-0401M) included oversight of a Settling Defendant conducting environmental sampling (e.g., soil, groundwater, sediment, surface water, subslab soil gas and indoor air), related data gathering and split sampling, in areas of interest to EPA, and the preparation of baseline human health and ecological risk assessments (HHRA/ERA) for the Site. Baseline risk assessments were previously prepared for this Site in March 2004 using sampling data collected prior to 2002. Due to an error, the 2004 baseline human health risk assessment was revised and "page-changes" to correct the error were published in February 2006.

The objective of this report is the presentation of a revised baseline HHRA/ERA for the Southwest Properties, incorporating soil, groundwater, subslab soil gas and indoor air data collected in 2010, 2011 and/or 2013. This objective has been addressed by evaluating site characterization data from soil, groundwater, subslab soil gas, indoor air, surface water, and sediment samples from the Southwest Properties.

The text of the report is presented in the following sections:

- **Section 1.0 - Introduction:** This section presents a description of the Southwest Properties, including the environmental setting, geology, hydrogeology and surface hydrology, background information on Site history, relevant previous investigations, and the study objectives;
- **Section 2.0 - Site Investigation:** This section describes the scope and methods of field studies, laboratory investigations and data validation, and discusses the nature and extent of contamination;

- **Section 3.0 - Baseline Human Health Risk Assessment:** This section evaluates the baseline human health risks associated with the Site;
- **Section 4.0 - Baseline Ecological Risk Assessment:** This section evaluates the baseline ecological risks associated with the Site;
- **Section 5.0 - Summary and Conclusions:** This section summarizes the report findings and describes the conclusions of the field investigation, HHRA, and the ERA; and
- **Section 6.0 - References:** This section contains the reference citations for the Executive Summary and Sections 1 through 5.

Volume I of this report also contains the figures and tables referred to in the text for the Executive Summary and Sections 1 and 5. Volume II contains tables for Section 3 (the baseline HHRA) and Section 4 (the baseline ERA). A third volume contains the appendices that provide analytical results (Appendix A), HHRA supporting information (Appendix B), ERA supporting information (Appendix C), the Risk Assessment Guidance for Superfund (RAGS) Part D tables for the vapor intrusion pathway at the existing Aberjona residence (Appendix D) and additional supporting information (Appendix E).

The remainder of this section of the report contains a discussion of the objectives of the project (Section 1.2), historical and investigation information relative to the Southwest Properties (Section 1.3), a description of the Southwest Properties area (Section 1.4), and the geologic/hydrogeologic setting (Section 1.5).

1.2 Project Objectives

The overall purpose of this report is to determine if contamination at the Site poses potential risks to human health and the environment. The general objectives are summarized below:

- Identify the contaminated environmental media and contaminants of potential concern (COPCs) at the Southwest Properties;

- Identify potential pathways of exposure and potential toxicological effects of contaminated environmental media at the Southwest Properties; and

- Identify sampling locations at the Southwest Properties Site where COPC concentrations in environmental media do and do not appear to pose potential risk to human and ecological receptors, based on exposure and toxicity assumptions.

A field sampling program conducted by the Settling Defendant at the request of EPA was designed to collect the data needed to augment existing data and meet the objectives described above. Sampling objectives and design are described in Section 2.0 of this report. This document addresses the study objectives related to human and ecological receptors.

1.3 Southwest Properties History and Previous Investigations

The Site is primarily comprised of three contiguous parcels of land known as Aberjona Auto Parts (Aberjona property, 6.5 acres), Whitney Barrel (Whitney property, 2.7 acres), and Murphy's Waste Oil (Murphy property, 3.6 acres), and is approximately 13 acres. The Site is located in Woburn, Massachusetts, as shown on Figure 1-1.

The Site is part of the 2nd operable unit (OU-2) of the Wells G&H Superfund Site, which is comprised of approximately 330 acres bounded by Route 128/Interstate 95 to the north, the Boston and Main (B&M) Railroad to the west, Interstate 93 to the east and Salem and Cedar Streets to the south (Figure 1-1). The Site is situated within the southwestern corner of the Wells G&H Superfund Site.

The Site boundary is approximately rectangular in shape with its long axis oriented approximately northeast-southwest along Salem Street (See Figure 1-2). A wetland area known as the Murphy Wetland lies between the upland portions of the Murphy, Whitney, Wildwood and Aberjona properties, and the Aberjona River flows north to south along the eastern boundary of the Site next to the Aberjona property. The B&M railroad abuts the Site to the west next to the Murphy property and Murphy Wetland. Salem Street abuts the Site to the south. The Wildwood

property, which is one of five source area properties associated with Operable Unit 1 of the Wells G&H Superfund Site, generally abuts the Site to the north. Three industrially-zoned properties with wood-framed structures that appear to be former residences abut the Murphy's Waste Oil parcel to the southwest of the Site.

OU-2, also referred to as the Central Area, was identified by EPA in the September 14, 1989 Wells G&H Record of Decision (ROD) as an area requiring further evaluation. A Remedial Investigation and Feasibility Study (RI/FS) of the Central Area was undertaken by several Settling Defendants pursuant to a September 8, 1991 Consent Decree (Decree), which specified the obligations for each Settling Defendant, and specifically identified the three Southwest Properties (Aberjona Auto Parts, Whitney Barrel, and Murphy's Waste Oil) as part of the Central Area. A separate RI of the Southwest Properties was conducted by Remediation Technologies, Corporation (RETEC) on behalf of one of the Settling Defendants (Beatrice Corporation) and presented in the *Draft Remedial Investigation, Southwest Properties, Wells G&H Superfund Site, Woburn, Massachusetts*, dated February 16, 1994 (1994 Draft RI). One of the objectives for the RETEC work was to gather the data necessary for EPA to prepare a baseline risk assessment for the Site to assess the need for remedial action. EPA's review of the Southwest Properties RI found significant deficiencies that required additional data gathering to support EPA's risk assessment. The Settling Defendant addressed the deficiencies through the preparation of a Supplemental Remedial Investigation Report (RETEC, 2003). EPA used these data to prepare a baseline HHRA/ERA in March 2004, which was revised in February 2006.

EPA requested further investigation and delineation of potential source areas at each of the Southwest Properties, and approved a sampling plan prepared by the Settling Defendant in September 2010. The Settling Defendant collected supplemental soil, groundwater and subslab soil gas data between 2010 and 2013, including subslab soil gas and indoor air data at the existing Aberjona residence during two seasonal rounds of sampling in 2013. The 2010/2011/2013 data have been combined with available historical data, as applicable, and evaluated in this baseline HHRA/ERA. The following sections describe historical activities that occurred at the properties prior to the 2010/2011/2013 sampling events.

1.3.1 Wells G&H

Wells G&H were municipal potable water supply wells developed by the City of Woburn in 1964 and 1967, respectively, in response to urban growth during the 1960s. The wells, screened in the Aberjona aquifer in deep overburden, were capable of supplying two million gallons of water per day, but were initially intended only for use during times of water shortage or emergencies. Local officials estimate that 27 to 28 percent of the community's water supply was provided by Wells G&H.

Local records indicate that the water from Wells G&H exhibited high concentrations of manganese and iron, which resulted in unpleasant taste and odor. Prompted by citizens' complaints concerning water quality, and in order to meet anticipated increased demand for water, the City of Woburn examined the feasibility of treating the water from Wells G&H in 1974. However, treatment was not implemented.

On May 4, 1979, 184 55-gallon drums containing polyurethane and toluene diisocyanate were found on a vacant lot located on Mishawum Road on property owned by the Massachusetts Bay Transportation Authority (MBTA). The drums were removed by unknown parties during negotiations with the Massachusetts Department of Environmental Quality Engineering (DEQE) (now the MassDEP). This incident prompted DEQE to sample the nearest downgradient water supply (i.e., Wells G&H) as a precautionary measure.

Several chlorinated volatile organic compounds (VOCs) including 1,l,l-trichloroethane (1,1,1-TCA), trans-1,2-dichloroethene (trans-l,2-DCE), tetrachloroethene (PCE), trichloroethene (TCE), chloroform, and trichlorotrifluoroethane were detected by DEQE in water from Wells G&H at concentrations ranging from 1 to 400 parts per billion (ppb). Wells G&H were subsequently shut down on May 21, 1979, forcing the City of Woburn to use Metropolitan District Commission (MDC) water (which originates from the Quabbin Reservoir) to supplement its public water supply. Currently, the MDC (now the Massachusetts Water Resources Authority or MWRA) supplies approximately one third of the city's water needs (approximately two

million gallons per day). The remainder, approximately four million gallons per day, is supplied by the Horn Pond Well Field to the south of Salem Street (TRC, 2002).

As a result of the contamination at Wells G&H and disposal problems discovered at the nearby Industri-Plex Site, an EPA contractor, Ecology and Environment, Inc. (E&E), was directed to conduct a hydrogeologic investigation and groundwater quality evaluation of a ten square-mile area east and north of Wells G&H. The purpose of this investigation was to determine the extent and degree of contamination, and to identify the sources of contamination. Based on the direction of groundwater flow, areal extent of groundwater contamination, and site inspections of 17 active and inactive facilities within the ten square-mile area, E&E identified the general source areas for TCE, trans-l,2-DCE, 1,1,1-TCA, and PCE detected at Wells G&H to be within a one square-mile area surrounding the wells. The contamination at the Industri-Plex Site was not linked with groundwater contamination found at Wells G&H. EPA developed a Hazard Ranking System (HRS) score for Wells G&H utilizing E&E's preliminary investigations and the analytical information provided by the DEQE. Wells G&H was listed on the National Priorities List (NPL) on December 21, 1982, and became known as the Wells G&H Superfund Site.

In May 1983, as a result of E&E's investigations, three administrative orders pursuant to Section 3013 of the Resource Conservation and Recovery Act (RCRA) were issued to W.R. Grace and Co., Inc. Cryovac Division (Grace), UniFirst Corporation (formerly Interstate Uniform Services Corporation; UniFirst), and Beatrice Foods, Inc. (Beatrice).

These orders required submittal of proposals by each company for the sampling, analysis, monitoring, and reporting that would address the problem of possible groundwater contamination on or emanating from their properties. Groundwater monitoring programs and related data gathering were subsequently initiated by the three companies at their respective properties.

On March 24, 1987, the EPA authorized Foster Wheeler (formerly Ebasco Services Incorporated) to conduct a Supplemental RI/FS for the Wells G&H Superfund Site in Woburn, Massachusetts. The Foster Wheeler Supplemental RI was conducted at the Wells G&H Superfund Site from September 1987 through January 1988. The results of the Foster Wheeler

Supplemental RI data were used with previously collected data to perform the FS. The Foster Wheeler Supplemental RI was also used to finalize an Endangerment Assessment document.

Foster Wheeler's Supplemental RI activities included collection of soil and groundwater samples from properties that the EPA identified as potential sources of the groundwater contamination at Wells G&H. These properties included W.R. Grace and Co., Inc. (Grace), UniFirst Corporation (UniFirst), Olympia Nominee Trust (Olympia), Wildwood Conservation Corporation (Wildwood), and New England Plastics Corporation (NEP). Surface water and sediment samples were also collected in the Aberjona River to provide additional data for the Endangerment Assessment.

The Foster Wheeler Supplemental RI indicated the presence of five likely groundwater contamination areas in the vicinity of Wells G&H. The likely source areas for each of these plumes were the Grace, UniFirst, Wildwood, NEP and Olympia properties.

In September 1989, EPA issued a ROD for the Wells G&H Superfund Site. The ROD required, among other things, that groundwater contamination beneath the Grace and UniFirst properties be remediated by extracting the groundwater and removing the contamination (EPA, 1989).

A Decree was signed by EPA and the Settling Defendants in 1991. The Settling Defendants then began work on respective areas of the Wells G&H Superfund Site. The five facilities that were identified as sources of contaminants and define Operable Unit 1 (OU-1) are located on the properties of Grace, UniFirst, Wildwood, NEP, and Olympia (also known as the Source Area Properties).

Primary contaminants include VOCs, lead, pesticides, polychlorinated biphenyls (PCBs), and polycyclic aromatic hydrocarbons (PAHs).

EPA took responsibility for the Aberjona River Study (OU-3) for the Wells G&H Superfund Site. The Aberjona River Study was designed to investigate the nature and extent of contamination in the Aberjona River sediments and surface water as well as evaluate potential

human and ecological risks. Because the Aberjona River flows from north to south through both the Industri-Plex and Wells G&H Superfund Sites and data obtained from studies at the Industri-Plex (North of Route 128) and Wells G&H (South of Route 128) Superfund Sites indicated that the Aberjona River at both sites contained similar Contaminants of Concern, EPA concluded that a divided approach to the river and wetlands was no longer reasonable or efficient. Hence, EPA merged the Wells G&H Aberjona River Study with the Industri-Plex Operable Unit 2 (OU-2) Multiple Source Groundwater Response Plan (MSGRP) Remedial Investigation/ Feasibility Study (RI/FS).

In September 2004, EPA completed the Wells G&H OU-3 Revised Aberjona River Study Baseline Risk Assessment (EPA, 2004). In March 2005, EPA completed the Industri-Plex OU-2 (including Wells G&H OU-3) MSGRP RI. This comprehensive RI describes the contamination and risks along the Halls Brook Holding Area (HBHA) and Aberjona River from Industri-Plex Site to the Mystic Lakes, and how contamination is migrating along the river system. The March 2005 RI merged and refined the baseline risk assessments from Industri-Plex to the Mystic Lakes along the Aberjona River (EPA, 2005).

In June 2005, EPA prepared and released the Industri-Plex OU-2 (including Wells G&H OU-3) Feasibility Study (FS), and Proposed Plan. On January 31, 2006, EPA released the Industri-Plex OU-2 (including Wells G&H OU-3) ROD.

The groundwater aquifer underlying the Wells G&H Superfund Site is not currently used as a municipal drinking water source. The objectives listed in the Wells G&H Superfund Site ROD include restoring the aquifer to drinking water standards. The City of Woburn has expressed interest in having the source available for the future. The MassDEP's Groundwater Use and Value Determination (MassDEP, 2004) assigned a "medium" use and value for the Site aquifer, based on a balanced consideration of several factors, and contemplated future use of the aquifer for domestic and industrial purposes. This determination was applied in the 2005 Industri-Plex OU-2 (including Wells G&H OU-3) MSGRP RI (EPA, 2005).

1.3.2 Southwest Properties

The September 1989 ROD for the Wells G&H Superfund Site "calls for a study of the central aquifer area to determine the most effective way of addressing contamination in the Central Area" (EPA, 1989). The approximate boundaries of the Central Area (or OU-2), as referenced in the ROD, are delineated in Figure 1-3. The ROD states that the objectives of the Central Aquifer/Aberjona River Study include but are not limited to the following:

- Define the nature and extent of contamination in the Aberjona River;
- Define the upgradient introduction of contaminants to the Aberjona River;
- Refine the present understanding of the interaction of the Aberjona River and the aquifer systems on the Site;
- Evaluate the effectiveness of pump and treat as a remedial alternative for the cleanup of contaminated groundwater in the Central Area;
- Evaluate the impact of pumping the central aquifer on the Aberjona River and associated wetlands;
- Identify and evaluate innovative remedial technologies for aquifer restoration, e.g., in-situ bioremediation; and
- Evaluate the mobility of contaminants including semivolatile organics and metals under ambient and pumping conditions.

The work and division of Settling Defendant responsibility for the above objectives are set forth pursuant to the Decree between Beatrice, UniFirst, Grace, NEP, EPA, and MassDEP.

The Decree included the Murphy, Whitney, and Aberjona properties located south of the Wildwood property and west of the Aberjona River (Southwest Properties) within the Wells G&H Superfund Site.

The inclusion of the Southwest Properties necessitated an evaluation of soil and groundwater at those properties, which had not been subject to as much prior investigation and interpretation as the Source Area Properties. RI work was undertaken in the Central Area by GeoTrans, Inc. of

Harvard, Massachusetts (GeoTrans) on behalf of Grace, Beatrice, UniFirst, and NEP. This joint RI work included background information on the Southwest Properties. However, a separate RI of the Southwest Properties was conducted by Remediation Technologies, Corporation (RETEC) on behalf of one Settling Defendant (Beatrice) and presented in the *Draft Remedial Investigation, Southwest Properties, Wells G&H Superfund Site, Woburn, Massachusetts*, dated February 16, 1994 (RETEC, 1994). One of the objectives for this work was to gather the data necessary for EPA to prepare a baseline risk assessment for the Southwest Properties to assess the need for remedial action. EPA's review of the Southwest Properties RI found significant deficiencies that required additional data gathering to support EPA's risk assessment, which were communicated to Beatrice in two detailed requests for additional data dated February 22 and October 15, 2000, respectively. In response, RETEC prepared a Sampling and Analysis Plan (SAP) for a Supplemental Remedial Investigation of the Southwest Properties dated July 19, 2002, which, following EPA commentary, was updated with page insert revisions dated September 19, 2002. The SAP as revised was conditionally approved by EPA in a letter dated October 18, 2002.

The Settling Defendant (Beatrice) conducted a Supplement RI to update and supplement data previously collected at the Southwest Properties. The results of the Supplemental RI are documented in the *Supplemental Remedial Investigation Report, Southwest Properties, Wells G&H Superfund Site, Woburn, Massachusetts*, prepared by the RETEC Group, Incorporated on behalf of the Beatrice Company (RETEC, 2003). Please refer to this document for additional information on the associated field investigation, nature and extent of contamination and contaminant fate and transport as presented by the Settle Defendant.

On behalf of EPA, TRC performed oversight of the Settling Defendant's Supplemental Remedial Investigation field activities, including split-sampling. The results of the split-sampling performed by TRC are documented in TRC's split-sampling report (TRC, 2004). EPA applied the relevant data documented in the 2003 Supplemental Remedial Investigation Report towards a draft *Baseline Human Health and Ecological Risk Assessment Report, Wells G&H Superfund Site, Southwest Properties, Operable Unit 2, Woburn, Massachusetts* in 2004, which was revised in February 2006.

In response to EPA's May 14, 2009 draft comment letter (Appendix E.4) on the 2003 Supplemental RI for the Southwest Properties, AECOM Technical Services, Incorporated (AECOM) conducted additional investigation and evaluation activities at each of the southwest properties between 2010 and 2013, including two seasonal rounds of subslab soil gas and indoor air sampling at the existing Aberjona residence in 2013. The primary objectives of the Supplemental RI were to address data gaps identified in previous investigation activities by EPA and evaluate current contaminant conditions at the Site. A description of the Supplemental RI is provided in AECOM's work plan (AECOM, 2010).

1.4 Site Description

Land use at and in vicinity of the Southwest Properties is highly developed with light commercial and light industrial areas bordering the wetlands area associated with the Aberjona River floodplain. Currently, the Aberjona property includes a fenced auto storage yard, located within the former salvage yard. An existing residence (the existing Aberjona residence) is also located outside the fenced auto storage yard. The Whitney property is occupied by a variety of small businesses (e.g., landscaping). The Murphy property is leased by CHES, and is a registered Treatment, Storage, and Disposal Facility (TSDF) under RCRA, currently used for treatment and storage of waste oil.

1.4.1 Parcel-by-Parcel Description

The following summarizes relevant descriptive and background information for each parcel in the Southwest Properties: Aberjona, Whitney, and Murphy properties. Table 1-1 provides a site description and history summary for each of the Southwest Properties.

1.4.1.1 Aberjona Auto Parts Property (270-280 Salem Street, Woburn, MA)

The Aberjona property is 6.51-acres that abuts the Aberjona River to the northeast, Salem Street to the southeast, the Whitney property to the southwest, and the Wildwood property to the northwest. There are four buildings on the Aberjona property. The largest of these buildings housed the former auto parts store and offices. The back portion of the building was used for

storage and removal of parts (i.e., the repair area). This portion of the building along with the area north-northeast of the existing residence and utility easement north of the indoor ice skating rink, falls with the Federal Emergency Management Agency (FEMA) 100-year floodplain (City of Woburn, Tax Map #38, 2013). The current owner has cleared the property of debris and the former salvage yard is currently used for temporary storage of automobiles. The eastern half of this building currently houses an auto repair shop. The western portion of the building houses a canine daycare operation, a private athletic training facility and storage space. The other three buildings on the property are a house (the existing Aberjona residence), detached garage and an indoor ice skating rink. Most of the property is a fenced auto storage yard or fenced exercise area for the canine daycare operation, except for the residence's yard, a small parking area along Salem Street, and the largely paved triangular parcel housing the ice skating risk adjacent to the Whitney property. The current ground surface is fill material ranging from six inches to five feet in thickness over the original ground surface. Environmental data for the Aberjona property has been obtained by work conducted by EPA and by the Settling Defendant.

1.4.1.2 Whitney Barrel Property (256 Salem Street, Woburn, MA)

To the west of the Aberjona property is the 2.67 acre former Whitney Barrel Company property. Although the barrel company is no longer in operation at the Whitney property, the long rectangular building that formerly housed the barrel company is currently occupied by several companies (e.g., landscapers, automotive glass company). Wetland areas surround the property to the northwest and west, and fill material has been placed over the original ground surface over the remainder of the property. The property falls nearly entirely within the FEMA 100-year floodplain (City of Woburn, Tax Map #38, 2013). The open area around the long rectangular building is used intensively by the leases for business operations (temporary storage, parking, etc.) and in some areas brick, wood and metal debris can be found. The area also includes old automobiles. Environmental data for the Whitney property has been generated by work conducted by EPA and by the Settling Defendant.

1.4.1.3 Murphy Waste Oil Property (252 Salem Street, Woburn MA)

The Murphy property lies to the west of the Whitney property and to the east of the B&M Railroad and is 3.6 acres. It is predominantly covered by fill. North and east of the fence that surrounds the waste oil facility is a wetland area. Limited portions of the property adjacent to the wetland fall within the FEMA 100-year floodplain (City of Woburn, Tax Map #37 & #38, 2013). The foundation of a former building occupies the northern portion of the property. The current oil storage facility, which was constructed above the former "oil pit", is a single building within the confines of the fence on the northwest side of the property. The building is primarily used for equipment storage, but has a small indoor office. The area within the fence is primarily covered with pavement. The building on the outside of the fence is used for storage. Environmental data for this property were collected by EPA and CHES.

1.5 Geologic/Hydrogeologic

1.5.1 Local Geology

The area in the vicinity of the Southwest Properties is underlain by unconsolidated glacial deposits that unconformably overlie crystalline bedrock (GeoTrans, 1994). The Aberjona River abuts the Southwest Properties immediately to the east. The Southwest Properties are situated within a portion of the western portion of the Aberjona River Valley. The following provides a brief description of the geology of the Aberjona River Valley by former production wells G&H, as well as geologic conditions present specifically within the Southwest Properties. Figure 1-4 contains a surficial geology map of the Site area that shows the surficial distribution of the unconsolidated deposits and bedrock outcrops. Figure 1-5 contains a bedrock geologic map of the Site area.

1.5.1.1 Geology of Central Area and Aberjona River Valley by Former Production Wells G&H

The unconsolidated deposits at the edges of the Aberjona River Valley are primarily ground moraine deposits. Within the Eastern Uplands, two varieties of till have been identified, a lodgment till and an ablation till. The lodgment till lies directly on the bedrock surface and is as much as 30 feet thick. The lodgment till was deposited at the base of the glacial ice, is very densely packed, generally has low permeability, and does not easily yield water to wells. Overlying the lodgment till is a thin layer of ablation till. The ablation till has a more sandy texture and is less densely packed than the lodgment till. In the Eastern Uplands, the ablation till generally exists above the water table (GeoTrans, 1994).

The low lying western portion of the Central Area Aquifer is comprised of stratified outwash deposits. Geologic logs of wells and borings indicate that within the buried bedrock valley, the outwash deposits generally overlie the bedrock surface directly. In some areas, there is a thin layer of lodgment till between the outwash deposits and bedrock surface (GeoTrans, 1994).

The swamp deposits consist of decayed vegetal matter, silt, sand, and possibly clay. These deposits generally lie at the surface, except where covered by artificial fill, and are found within the wetlands that border the Aberjona River and its tributaries. Based on geologic logs from wells drilled through the swamp deposits, the thickness, which varies considerably and is probably a result of the surface topography of the outwash deposits, is generally less than 5 feet (GeoTrans, 1994).

The stratified drift deposits fill the Aberjona River Valley, make up the Central Area Aquifer, and are up to 130 feet thick. The stratified drift deposits are well sorted and possess much higher hydraulic conductivity than the till, ranging from 0.1 feet per day in the finer grained deposits to 350 feet per day in the gravelly layers (Myette et al., 1987). City of Woburn public water supply wells G&H and the J. J. Riley supply wells were constructed in the stratified drift because the high hydraulic conductivity of these deposits and proximity to the Aberjona River allowed large

well yields (GeoTrans, 1994).[3] Several other industrial supply wells were operated in the stratified drift deposits north of the Wells G&H Superfund Site (Delaney and Gay, 1980).

The bedrock underlying the Wells G&H Site has been mapped as Salem Granodiorite, Dedham Granite, and undifferential metavolcanics (Barosh et al., 1977). The underlying bedrock surface rises steeply from an elevation less than –100 feet National Geodic Vertical Datum (NGVD) along the buried valley axis, to an elevation greater than 100 feet NGVD near the intersection of Washington Street and Route 128. In general, available data indicate the bedrock is generally competent and is not extensively fractured, but contains localized fracture zones capable of yielding water to wells (GeoTrans, 1994). Figure 1-5 contains a bedrock geologic map of the Site area.

The hydraulic conductivity of the bedrock is generally low and, in general, potential well yields would be low. Localized areas within the Wells G&H Superfund Site, however, have been discovered where water yields have been sufficient for well installation such as Johnson Brothers greenhouses and New England Plastics (GeoTrans, 1987 and 1994; HMM, 1990).

1.5.1.2 Geology of Southwest Properties

The local geology within the Southwest Properties is generally consistent with the low lying western portion of the Aberjona River Valley where the geology is comprised of stratified outwash deposits and overlie the bedrock surface directly. The Supplemental RI Report (RETEC, 2003) included a composite summary of geology of the Southwest Properties based on work performed by RETEC and others. A copy of RETEC's geologic cross-sections and associated cross-section location map included in the Supplemental RI Report are reproduced herein as Figures 1-6 and 1-7.

[3] The J.J. Riley facility is a former tannery located at the corner of Salem Street and Wildwood Road to the west of the Southwest Properties.

The natural overburden within the Southwest Properties is composed of stratified drift and swamp deposits (RETEC, 2003). As indicated in Figure 1-7, the Southwest Properties are underlain by a basal glacial till, stratified drift deposits and a thin, relatively continuous layer of fill material near the ground surface (RETEC, 2003). The stratified drift consists of interbedded sand, gravel, silt and swamp deposits in select areas of the Site. The fill layer generally consists of light gray to dark brown sand mixed with subangular gravel, silt and/or varying amounts of brick, metal and wood debris (RETEC, 2003).

As indicated in the Supplemental RI Report (RETEC, 2003) and consistent with the previously noted axis of the buried bedrock valley in the approximate area of the Aberjona River, the bedrock surface slopes from west to east across the Wildwood property and southern and western portion of the Southwest Properties. The bedrock surface mapped by RETEC also indicates a sub-trough extending approximately north-south beneath the Aberjona property. Bedrock at the Southwest Properties has been described as consistent with the Central Area and generally includes shallow metamorphosed diorite and granitic intrusions overlaying gabbro-diorite (Murphy property), green and gray gabbro-diorite (Whitney property) and gabbro-diorite transitioning to grano-diorite (Aberjona property) based on data evaluated during the Supplemental RI (RETEC, 2003).

1.5.2 Regional Hydrogeology

The Aberjona River, which has its headwaters in the Town of Reading and empties into the Mystic Lakes in the Town of Winchester, flows north to south through the Site. Relatively small amounts of groundwater enter the Aberjona River Valley from upgradient areas north of Interstate 95 (Route 128), and exit the narrow southern end of the valley south of Salem Street. A 38-acre wetland area exists along both sides of the Aberjona River that is located within the 100-year floodplain of the Aberjona River (EPA, 1989). The drainage basin area of the Aberjona River upstream of the Salem Street Bridge, which marks the downstream end of the Wells G&H Site, is approximately seven square miles (GeoTrans, 1994).

The United States Geological Survey (USGS) maintains a surface water gauging station in Winchester, Massachusetts, located about four miles downstream of the Salem Street Bridge. According to the USGS Water Data Report for 2011 for the Aberjona River at Winchester, gauging data has been collected at this station since 1939 (USGS, 2012). The annual mean river discharge between 1939 and 2011 was 31.7 cubic feet per second (cfs). Extreme flows at Winchester during the period of record range from the lowest daily mean of 0.25 cfs on October 10, 1950, to the highest daily mean of 1,420 cfs on May 15, 2006 and March 15, 2010 (USGS, 2012). Since the early 1940s, the trend shows an increase in both the frequency and magnitude of high flow events (USGS, 2012).

River sediments are composed of silt and sand ranging in thickness from 0.5 to 2 feet and are underlain by peat averaging 7 feet in thickness. The peat, a relatively loose nearly saturated material, permits groundwater discharge to the Aberjona River (EPA, 1989).

1.5.3 Local Hydrogeology

The following provides a brief description of the geology of the Central Area (OU-2), as well as geologic conditions present specifically within the Southwest Properties.

1.5.3.1 Central Area and Aberjona River Valley by Former Production Wells G&H Hydrogeology

Under non-pumping conditions, groundwater within the boundaries of the Wells G&H Site generally flows laterally in the unconsolidated deposits and bedrock from the edges of the valley toward the center of the valley. In the center of the valley and near the Aberjona River, groundwater which originated in the upland areas converges with groundwater flowing from north of Route 128 and generally assumes a more southerly flow direction approximately parallel to the course of the Aberjona River (GeoTrans, 1994). Water table contours and bedrock potentiometic surface mapping conducted in September 1993 indicated groundwater flow generally from the north-northwest (Wildwood property), toward the Southwest Properties and ultimately the Aberjona River. A shift in the shallow groundwater contours, to more east-

northeasterly flow pattern across the Southwest Properties and toward the Aberjona River, is depicted in the vicinity of the Murphy property (GeoTrans, 1994).

In 1987, the USGS completed a hydrogeologic investigation of the central Aberjona River valley and evaluated the area of influence and zone of contribution to City of Woburn municipal Wells G&H. Figures 1-8 and 1-9 illustrate the area studied by the USGS and present representative cross-sections showing the generalized stratigraphy and a conceptual model of the groundwater flow system.

According to the USGS, groundwater in the Aberjona River valley in the vicinity of Wells G&H is present mainly in a 0.5-1.0-mile wide stratified drift aquifer that fills a deep, narrow bedrock channel. The USGS developed a generalized stratigraphy for the central Aberjona River valley that included four stratigraphic layers (with the upper three layers considered the local aquifer). The uppermost stratigraphic layer consists of sand, silt, clay, and deposits of peat, and has a thickness of 0 to 30 feet. It is underlain by an intermediate layer of fine-to-coarse sand that has a thickness of 10 to 50 feet.

Groundwater in the stratified drift is unconfined, and water levels fluctuate continuously in response to recharge and discharge. The water table is generally at or near the ground surface in most of the low-lying areas. The direction of groundwater flow is typically inward toward the central axis of the river. Under non-pumping conditions, groundwater discharges to the river and adjacent wetlands. Appreciable vertical hydraulic gradients were generally only observed near the outer river valley walls (downward) or directly adjacent to the river channel (upward). Groundwater flow elsewhere was primarily horizontal (GeoInsight, 2000). The lowermost aquifer layer, where Wells G&H were screened, consists of 20 to 50 feet of course sand and gravel. A layer of fine grained sand and silt (up to 40 feet thick) occupies the deepest portions of the river valley and is situated directly on top of bedrock (GeoInsight, 2000).

1.5.3.2 Southwest Properties Hydrogeology

With respect to the Southwest Properties, groundwater generally flows across the Southwest Properties Site toward the Aberjona River and associated wetland areas. The surface configuration of the Southwest Properties and vicinity reflects the underlying bedrock surface, including the potential for the bedrock valley to be fault-controlled by a north-south fault under the Aberjona River Valley. Many bedrock outcrops are present in the highlands to the east of the river valley. Vertical hydraulic gradients are typically downward on the valley flanks and upward in the center of the valley (RETEC, 2002).

Depth to groundwater at the Southwest Properties varies, but ranges from 5 to 9 feet from the ground surface. The general direction of shallow groundwater flow is to the east toward the Aberjona River. Historically, the influence of John J. Riley (J.J. Riley) pumping well caused overburden groundwater to locally flow to the north, toward the Wildwood property, within the northwest portion of the Southwest Properties (RETEC, 2002). Under pumping conditions, a groundwater divide was interpreted to extend within the vicinity of MW-4S, B-7 and BWS-2 (GHR, 1988).

Locally, the groundwater table is influenced by river stage, principally at the Aberjona property. Based on gauging data collected in December 2002, a groundwater trough, resulting in shallow groundwater flow away from the river, was noted within the central portion of the Aberjona property (RETEC, 2002). The trough was interpreted to be the result of localized higher groundwater elevations in the vicinity of shallow wells adjacent to the river (e.g., S-77SS and AB-4SS) and was not evident in the intermediate and deep overburden zones in 2002 (RETEC, 2002).

Several factors including the wetland and associated stream to the rear of the Murphy and Whitney properties, the sewer line at the rear of the Whitney property and seasonal fluctuations are also likely to locally influence shallow groundwater flow patterns. Monitoring well gauging data collected throughout the Southwest Properties (Table 1-2), Wildwood property (Appendix E.5) and Central Area (Appendix E.6) between 2011 and 2013 indicate an apparent transient

mixing zone along the boundary between the Southwest Properties and the Wildwood property. The October 2011 well gauging data indicate that the majority of the shallow groundwater flow originates on the Wildwood property (i.e., vicinity of the BSSW-5/BW-5/BW-5R well cluster) and flows toward the north-northeastern portion of the Aberjona property. Conversely, the July 2013 data indicate shallow groundwater flow to the northeast, from the Southwest Properties toward the BW-16 and S-77 well clusters. This conclusion is consistent with the variable shallow groundwater flow patterns observed in September and November 1993 (RETEC, 1994). RETEC depicted a northeastern component of flow along the northern boundary of the Aberjona property in September 1993, shifting to a southeastern flow direction based on an interpretation of the November 1993 well gauging data.

For the deeper overburden and shallow bedrock, the October 2011 and July 2013 well gauging data suggest that the groundwater flow patterns are more consistently in an east to northeasterly direction (i.e., generally from BW-2 and BW-5 well clusters toward the BW-16 and S-77 well clusters). These data indicate that the dominate groundwater flow pattern is from the Wildwood property toward the northern portion of the Southwest Properties (Appendix E.5 and E.6).

SECTION 1 TABLES

Table 1-1
Site Description and History Summary
Southwest Properties
Wells G Superfund Site - OU-2
Woburn, Massachusetts

	Year(s)	Site Description / Activity
Aberjona Auto Parts	1949	Begin operation as an automotive repair facility and Gulf gasoline station.
	1960	Gulf gasoline station operations cease.
	1960	Property used for automative part and junk car storage.
	1961 - 1967	Repeated property violations related to open burning of junk automobiles and associated materials.
	1968	Warehouse built.
	1978	Sales area built.
	1980	Discharges to grease pit noted during site inspection. Grease pit connected to oil-water separator which drains to sanitary sewer.
	1987	MWRA issues letter stating that oil-water separator is not working properly and requires regular maintenance.
	2005	Began leasing portions of property. Junk automobiles and associated materials removed from property.
	2008	Ice skating rink built on portion of property.
	Present	Automotive repairs, storage, indoor/outdoor canine daycare, various leases and ice skating rink.
Whitney Barrel Company	1920s - 1930s	Property used for agricultural purposes (includes reported illegal poppy farming).
	1938 - 1950	Property used for storage.
	1950	Whitney Barrel Company begins drum and tank recycling and reconditioning activities: ● Interior (drum) and exterior (tank) cleaning and refurbishing operations. ● Interior included wash room with wash tank, drum storage and paint booth. Floor drains discharge to sanitary sewer. ● Drum contents were reportedly discharged directly to sanitary sewer.
	1960 - 1986	Series of fires at property with most destructive reportedly occurring in 1977 and 1979. Barrels contents related to fires.
	1979	Kingston Steel Barrel Company reportedly directed to discharge waste into sewer manhole.
	1979	Site inspections indicate spills and leaks of barrels and tanks to ground surface.
	1984	Barrel refurbishing operations cease.
	1990	MassDEP Release Incident Report indicates worker instructed to dispose of petroleum waste into sewer manhole
	1996	Hydraulic oil release occurred during flooding.
	Present	Property leased to multiple parties (e.g., landscapers, automotive glass company)
Murphy Waste Oil	1919	Woburn Oil Company begins operation: ● Depression in central portion of property ("oil pit") used for waste oil and filter disposal. ● Above-ground storage tanks in northern portion of property ("oil yard").
	1979	Waste oil spreading as standard dust suppression practice ceases.
	1987	Estimated 100 to 150 gallon fuel oil release in north-central portion of property.
	1989	Clean Harbors removes approximately 1,000 cy of material from "oil pit" are and constructs new waste handling facility.
	1993	Estimated 75 gallons of reclaimed oil release to unpaved gravel area, reponse actions taken and RAO in 1994.
	2001	LNAPL discovered in property monitoirng wells. Ongoing IRA under the MCP.
	Present	Clean Harbors operates current waste handling facility.

Notes:

* See Appendix E.5 for Wildwood property water level elevations (2011 and 2013) and Appendix E.6 for Central Area water level elevations (2011).

ft BMP - feet below measuring point

ft msl - feet above mean sea level

NA - not available or not applicable

[1] - Well was installed in December 2012.

[2] In the April 2011 event, the field crew inadvertently gauged well MW-008 instead of S83.

[3] In the October 2011 event, the field crew inadvertently gauged wells MW-011S/M/D instead of S83S/M/D.

[4] Well located on Wildwood Property but included include due to the proximity of the well to the Southwest Properties.

[5] Thick globules of petroleum-like product observed but could not measure thickness.

[6] Wells recently resurvyed. Revised MP elevations shown.

SO = shallow overburden T = till IO = intermediate overburden SR = shallow bedrock DO = deep overburden DR = deep bedrock

2.0 SITE INVESTIGATION

2.1 Field Investigation

In 2002 and 2001, the Settling Defendant (Beatrice) conducted a Supplemental RI to update and supplement data previously collected at the Southwest Properties. The results of the Supplemental RI are documented in the *Supplemental Remedial Investigation Report, Southwest Properties, Wells G&H Superfund Site, Woburn, Massachusetts*, prepared by the RETEC Group, Incorporated on behalf of the Beatrice Company (RETEC, 2003). Please refer to this document for additional information on the associated field investigation, nature and extent of contamination and contaminant fate and transport as presented by the Settle Defendant.
On behalf of EPA, TRC performed oversight of the Settling Defendant's Supplemental Remedial Investigation field activities, including split-sampling. The results of the split-sampling performed by TRC are documented in TRC's split-sampling report (TRC, 2004).
In response to EPA's May 14, 2009 draft comment letter (Appendix E.4) on the 2003 Supplemental RI for the Southwest Properties, AECOM Technical Services, Incorporated (AECOM) conducted additional investigation and evaluation activities at each of the properties between 2010 and 2013, including two seasonal rounds of subslab soil gas and indoor air sampling at the existing Aberjona residence in 2013. The primary objectives of the Supplemental RI were to address data gaps identified in previous investigation activities by EPA and evaluate current contaminant conditions at the Site. A description of the Supplemental RI is provided in AECOM's work plan (AECOM, 2010) and a brief summary is provided herein.

An iterative approach was used by the Settling Defendant to investigate the Southwest Properties. The Supplemental RI included installation and sampling of soil borings, groundwater monitoring wells and subslab vapor points, indoor air sampling, groundwater and light non-aqueous phase liquid (LNAPL) measurements, and test pit excavations and investigation of the drain line (e.g., Whitney Barrel Property). Soil, groundwater, surface water, sediment, subslab soil gas and indoor air sampling points investigated to date are depicted in Figure 2-1.

Soil Boring Sampling

A total of 46 soil borings were advanced throughout the Southwest Properties between November 15, 2010 and April 8, 2011 including the following:

- Aberjona Property – 8 soil borings
- Whitney Property – 24 soil borings
- Murphy Property – 14 soil borings

Soil borings were advanced using a GeoProbe® direct push drill rig or hand tools (e.g., hammer drill). Soil borings were advanced and soil samples were generally collected to evaluate surface soils (i.e., 0 to 2 feet below grade), soils at the water table and to evaluate the "worst case" subsurface material based on field screening, visual and/or olfactory observations. Soil borings were screened using a photoionization detector (PID) and samples were collected for laboratory analysis of VOCs, VPH, EPH, SVOCs, PCBs, dioxin-like PCB congeners, pesticides and/or metals analysis.

Monitoring Well Installation and Groundwater Sampling

Monitoring wells were installed throughout the Southwest Properties during Supplemental RI activities in pre-determined locations to address known data gaps (e.g., MR-206, WB-215 and WB-216) and based on field observations following consultation with the EPA. Groundwater water monitoring wells were constructed of 2-inch diameter Schedule 40 PVC with ten feet of 0.010-inch slotted screen that spans the water table. Each well was backfilled with an appropriate sand pack and bentonite seal.

Each of the monitoring wells underwent development in accordance with surge block techniques. Following a 14-day equilibration period and the collection of site-wide synoptic water level measurements, groundwater samples were collected from each of the newly installed monitoring wells as well as select existing monitoring wells as follows:

- Aberjona Property – 15 monitoring wells (5 newly installed)

- Whitney Property – 12 monitoring wells (7 newly installed)
- Murphy Property – 10 monitoring wells (3 newly installed)

Groundwater samples were collected in accordance with low-flow sampling procedures. Based on the historical presence of LNAPL in select wells at the Murphy property, alternative sampling methods (e.g., Teflon bailer) were employed if LNAPL was determined to be present. Groundwater samples were collected for laboratory VOCs, VPH, EPH, SVOCs, dioxin-like PCB congeners, pesticides, metals (total and dissolved), total organic carbon (TOC), chloride, nitrate, nitrite, sulfate, chemical oxygen demand (COD), methane, ethane and/or ethene analysis.

As described in the Revised Work Plan for Installation of Monitoring Wells and Monitored Natural Attenuation Groundwater Sampling (AECOM, 2013), additional monitoring wells were installed in 2013 to evaluate contaminant extents and natural attenuation parameters in advance of the Phase 1B investigation activities within OU-2. Supplemental well installation included the following:

- Aberjona Property – AB-1SR (shallow bedrock)
- Whitney Property – S-83DO (deep overburden) and S-83SR (shallow bedrock)

In addition, several monitoring wells (i.e., S-77SR, S-77DR, S-92SR, S-92DR, S-95SR, WW-100SR, WW-101SR and WW-102IO) were recently installed within the Wildwood property in accordance with the *Work Plan for Installation of River Monitoring Wells and Geophysical Investigation* (AECOM, 2012). Monitoring wells S-77SR (shallow bedrock) and S-77DR (deep bedrock), installed during the above noted monitored natural attenuation (MNA) investigation at the Southwest Properties, are also located within the Wildwood property, immediately north of the Aberjona property boundary (Figure 2-1). Due to the proximity of the well cluster to the Aberjona property boundary, the S-77 well cluster is discussed in association with the Southwest Properties. Groundwater monitoring wells were constructed of 2-inch diameter Schedule 40 PVC pursuant to the above noted work plans.

Groundwater samples were collected from each of the newly installed wells, as well as several existing monitoring wells located within the Southwest Properties and the adjacent Wildwood property, in July 2013. Analytical results associated with the Wildwood property are included in Appendix E.5. Groundwater samples were collected in accordance with low-flow sampling procedures. Groundwater samples were collected for laboratory VOCs, 1,4-dioxane, metals (total and/or dissolved) and MNA parameter (i.e., groundwater chemistry parameters, dissolved gases and microbial census) analysis.

Subslab Soil Gas Sampling

Subslab soil gas sample points were installed within existing structures at each of the commercial buildings at the Southwest Properties and at the existing Aberjona residence including the following:

- Aberjona Property – 4 subslab locations (garages and current office)
- Whitney Property – 5 subslab locations (drum cleaning and painting area)
- Murphy Property – 1 subslab locations (current onsite building)
- Existing Aberjona Residence – 1 subslab location (current occupied residence)

Subslab soil gas locations were installed to help identify sources beneath the buildings and to provide a preliminary indication of the potential vapor intrusion[4] pathway at each of the properties. Each of the locations was subsequently sampled for laboratory analysis for VOCs and air-phase petroleum hydrocarbon (APH) analysis. All subslab sampling locations were sampled once, except for the existing Aberjona residence location which was sampled twice (April 25, 2013 and August 30, 2013) to provide information on seasonal variability associated with the vapor intrusion pathway.

[4] Vapor intrusion is defined as the movement of VOCs from groundwater into soil gas and then into a building. Only VOCs present in indoor air as part of a complete vapor intrusion pathway are evaluated in the risk assessment.

Indoor Air Sampling

At the existing Aberjona residence, one basement and one first floor indoor air sampling location was identified. At the basement location, a sample (IA1-A) and a field duplicate (IA1-A-FD) were collected on April 3, 2013 and August 29, 2013 to assess seasonal variability associated with the vapor intrusion pathway. At the first floor location, in the kitchen at the top of the basement stairs, one sample (IA2-A) was also collected on April 3, 2013 and August 29, 2013. On the same days, an ambient air sample (AMB1-A) was collected from an upwind location to provide information on concentrations of VOCs in outdoor air in the vicinity of the residence.

Indoor air sampling was conducted to allow for a quantitative evaluation of the vapor intrusion pathway at the existing Aberjona residence. Each of the air samples was analyzed for VOCs and APH fractions/target compounds.

Whitney Drain Line Investigation

As described in the 2010 Supplemental RI work plan, the drain line connecting the former Whitney drum storage area to the municipal sewer system was investigated to determine the integrity of the drain line, surrounding soil characteristics and potential contaminant impacts. A test pit was excavated near the rear of the Whitney building to locate the presumably abandoned drain line. During initial excavation, the field PID instrument recorded elevated air-phase VOC concentrations within 15 feet of the exposed sewer pipe ranging from approximately 1,340 ppmv to over 9,999 ppmv. As a result, the field staff personnel upgraded PPE to include the use of half-faced respirators with organic vapor cartridges (Appendix E.1). Once the sewer pipe was encountered, the excavation activities continue north (toward the municipal sewer connection) to evaluate the integrity of the drain line. Excavated soils were inspected for visual and/or olfactory evidence of contamination and screened with a PID. Generally, groundwater was observed to be coincident with the approximate depth of the drain line, hindering evaluation of the drain line integrity. Attempts to conduct a video survey of the drain line were also unsuccessful due to blockage encountered in the line.

In general, observed portions of the drain line appeared to be intact and in relatively good condition; however evidence of impacts including the presence of black staining and/or elevated PID screening results (i.e., up to 2,249 ppmv) were observed within soil material excavated from adjacent to the drain line. Select soil samples were also submitted for laboratory VOCs, VPH, EPH, PCBs, pesticides and/or metals analysis.

2.2 Environmental Data Utilized

Environmental data collected during several sampling events conducted by property operators, Settling Defendant, and split samples collected on behalf of EPA by TRC were utilized to prepare the baseline human health and ecological risk assessment, including the AECOM Supplemental RI 2010/2011/2013 soil, groundwater, subslab soil gas and indoor air sampling data. The historical data used in the baseline risk assessment are contained in the following three main data source documents:

- RETEC 1994, *Draft Remedial Investigation, Southwest Properties, Wells G&H Site, Woburn, Massachusetts, 1994*.

- RETEC 2003, *Supplemental Remedial Investigation, Southwest Properties, Volumes I through XXIII, Wells G&H Site, Woburn, Massachusetts*. Prepared by the RETEC Group, Inc., Concord, Massachusetts, August 2003.

- TRC 2004, *EPA/TRC and RETEC Split Sample Comparison Report for the Wells G&H – Southwest Properties, Supplemental Remedial Investigation, Woburn, Massachusetts.* Prepared by TRC Environmental Corporation, Lowell, Massachusetts, February 2004.

Additional data for the Murphy property were obtained from:

- Clean Harbors 1998, *Corrective Action Investigation Report (Part II),* Volume I of I, Murphy's Waste Oil Services, Inc., Woburn, Massachusetts, *1998*.

- Clean Harbors 1996, *Corrective Action Investigation Report*, Volumes 1, 2, and 3. Murphy's Waste Oil Service, Inc., 252 Salem Street, Woburn, Massachusetts, April 15, 1996.

Groundwater data collected in 2011 from across the Site were used instead of the historical 2001/2002 groundwater data. Data collected in 2011 are more representative of current Site conditions.

Refer to Appendix A for media specific tables that summarize the data used to prepare the baseline human health and ecological risk assessment.

2.3 Data Validation

Data obtained as part of the Supplemental RI and associated TRC split data (RETEC, 2003; TRC, 2004) and recent AECOM Supplemental RI investigation were validated according to Region I, *EPA-NE Data Validation Functional Guidelines for Evaluating Environmental Analyses*, December 1996, as described in the Supplemental RI, TRC Split Report and the Quality Assurance Project Plan associated with AECOM's Supplemental RI work plan (AECOM, 2010). The validation guidelines were modified to accommodate the non-CLP methods. The respective analytical results are discussed in the 2003 Supplemental RI and the 2004 TRC Split Report.

Data obtained from the Clean Harbors 1998 Corrective Action Investigation Report (Part II) were not validated when published. EPA determined that within the limited circumstances of this project, validation of a representative subset of the analytical data may provide reasonable confidence in the quality of the data. EPA required that validation be conducted on a minimum of 25 percent of the total samples analyzed using EPA Tier II protocols, and 5 percent of the samples using EPA Tier III protocols, in accordance with EPA Region I data validation guidelines. However, no Tier III validation was performed due to lack of required data needed to perform Tier III. In almost all cases, only a limited Tier II validation was performed.

2.4 Data Treatment

This subsection discusses the use and treatment of the analytical data prior to use in the baseline human health and ecological risk assessment.

The following criteria were applied to the analytical data:

- If a value is not flagged, the value was used as reported (a detected value);
- If a value is flagged with "J", "EB", or "FB", the value was used as reported (a detected value);
- If a value is flagged with "R", the value was considered not to exist and was not used (a rejected value); and
- If the value is flagged with "U" or "UJ", the result was considered a nondetect (an undetected) value.

Prior to using analytical data for a primary sample with an associated field duplicate, the analytical values for the primary sample and the field duplicate were averaged together to provide a single set of values for the field duplicate pair. The following conventions were used for averaging field duplicate samples together:

- If both samples have detected values (flagged with "J" or unflagged), the average of the values was used. If one value or both values are flagged with "J", "EB", or "FB" prior to averaging, the resulting averaged value was flagged with "J", "EB", or "FB", as appropriate.
- If both samples have nondetected values (flagged with "U" or "UJ"), the lower value and its flag were used.
- If one sample has a nondetect value (flagged with "U" or "UJ") and the other sample has a detected value (flagged with "J" or unflagged) the following is done:
    - If the detected value is less than or equal to the nondetected value, the detected value and its flag were used; or

- If the detected value is greater than the nondetected value, the average of detected value and ½ the nondetected value were used. The resulting averaged value was flagged with "J".

- If one sample has a nonrejected value (flagged with "J", "U", "UJ", "EB", "FB" or unflagged) and one sample has a rejected value (flagged with "R"), the nonrejected value and its flag were used.

The range of detection limits was determined based on the individual sample-specific detection limit (or sample quantitation limit) for each analyte. Because of sample dilution and/or sample weights, laboratory detection limits for individual samples can be higher than the method-specified detection limits. Minimum and maximum SQLs were determined for each non-detect analyte using the sample's SQL. Instances where elevated detection limits were reported and their effect on the conclusions of the risk assessment have been discussed in the uncertainty section.

The frequency of detection is the number of samples with detected values per the number of samples analyzed. The number of samples with detected values was determined by totaling all samples with detected values. The number of samples analyzed was determined by totaling all samples with detected or nondetected values (flagged with "U", "UJ", "J" or unflagged). Rejected values (flagged with "R") were not included in the total number of samples analyzed. For field duplicate samples, only one value was used when determining the number of samples analyzed and the number of detected values (as determined using the procedure described above).

Arithmetic means were calculated using ½ the sample SQL substituted for non-detect values. 95-Percent Upper Confidence Limits (UCLs) were calculated using EPA's Pro UCL version 4.1. When the mean or 95-percent UCL was greater than the maximum value because of high or widely varying detection limits, or because a detected value is below the SQL (flagged with "J" on the laboratory report), or because a small data set was used, then the maximum detected result was used. Detected values below the SQL are considered to be estimated concentrations, but are

used in the risk assessments. A discussion of the impact of the use of maximum detected concentration on the risk assessment conclusions is provided in the uncertainty section.

2.5 Nature and Extent of Contamination

The following presents a summary of the nature and extent of chemicals detected in soil, sediment, groundwater, indoor air and subslab soil gas for the Site. This section summarizes significant potential sources of contamination, impacted media and the results of previous environmental investigations. Monitoring wells BSW-2, BW-2R, BOW-16, BSSW-16, BW-16R, and the S77 well cluster are located on the Wildwood property. Due to their close proximity to the Southwest Properties, they have been included in the following discussion.

For the purposes of this report, the discussion of the nature and extent of contamination is focused on all data collected to date. Previous discussions of Site data are included in the RI (RETEC, 1994), SAP (RETEC, 2002) and Supplemental RI (RETEC, 2003) prepared by RETEC. EPA used these data to prepare a baseline HHRA/ERA in March 2004, revised in February 2006 (EPA, 2006). In response to EPA's May 14, 2009 draft comment letter (Appendix E.4) on the 2003 Supplemental RI for the Southwest Properties, AECOM prepared a Supplemental RI work plan (AECOM, 2010) and conducted additional investigation and evaluation activities between 2010 and 2013.

Clean Harbors Environmental Services, Incorporated (CHES) has undertaken environmental investigation activities at the Murphy property. The early investigation activities are largely documented in the Corrective Action Investigation Report (CARP) dated April 15, 1996 (CHES, 1996). Ongoing Immediate Response Action (IRA) activities are also being conducted by CHES under MassDEP Release Tracking Number (RTN) 3-22144 in association with the recent detection of LNAPL the Murphy property. Please refer to these documents for additional information on the associated investigation, nature and extent of contamination and contaminant fate and transport.

2.5.1 Contaminant Sources

Previous environmental investigations have detected several potential contaminants of concern within Site media. These contaminants are associated with several known or potential sources/releases at each of the Southwest Properties. The following presents of summary of significant known or potential contaminant sources identified at each parcel in the Southwest Properties and the Murphy Wetland.

Aberjona Property

Aberjona began operations in the mid-1950s for the sale and reconditioning of used and wrecked automobiles, and was also a gasoline service station. The property is currently occupied by automotive repair shops, a landscaper, a residence, a recently constructed ice rink, a private athletic training facility, and a canine daycare operation. Wetland areas border the property to the north and west, including a portion of the area known as the Murphy Wetland (discussed below). Environmental investigation activities conducted to date have identified several know or potential sources of contamination. These include the following:

- Former gas station activities;
- Auto salvage yard operations;
- Unauthorized burning activities (cars, wood and seat cushions);
- Main garage area operations (including degreasing operations and use of a grease pit draining to an oil-water separator and ultimately the sewer system);
- Historic presence of underground storage tanks (USTs) (gasoline and waste oil); and
- Impacts from adjacent (upgradient) properties.

The contaminant sources at the Aberjona property tend to be related to the extensive history of use as an auto repair and storage facility. A gas station operated, mainly adjacent to the southern

portions of the main operations building, between approximately 1949 and 1960. The approximate locations of the pump island, filler pipes, and the gasoline and waste oil USTs are all within this portion of the property.

The property was used extensively for automobile and parts storage following filling of the wetlands north of the on-site buildings in 1959. Unauthorized burning of automobiles, wood and seat cushions is also believed to have occurred to the rear and north of the main garage building. Five notices were made by the Massachusetts Metropolitan Air Pollution Control District between 1961 and 1967 related to open burning of junked automobiles and associated debris (RETEC, 2003).

Operations occurring in and around the main garage also included dismantling of vehicles, use of an engine bay and back garage for parts cleaning, fluid removal, degreasing operations and temporary storage of waste oils. The main garage building has three floor drains that convey fluid discharges in the building to an oil-water separator. All fluids reportedly drained to the sewer system which extends westerly from the southern portion of the building toward the adjacent wetlands.

Whitney Property

To the west of the Aberjona property is the Whitney property. The company formerly conducted drum and tank recycling and reconditioning activities, with interior cleaning of drums and exterior cleaning of tanks. The barrel company is no longer in operation at the property; however the on-site building is currently occupied by several companies (e.g., landscapers, auto repair, and contractors). An automotive glass company occupies a separate building on the Whitney parcel. Wetland areas border the property to the northwest, west, and southwest, including an area known as the Murphy Wetland (discussed below). Fill material has been progressively placed over the original ground surface throughout the remainder of the property. Environmental investigation activities have identified several know or potential sources of contamination. These sources include the following:

- Drum cleaning operations (mainly near the rear of the building);
- Floor drains within the building (drum cleaning and painting operations area) draining to the sewer;
- Drum, tank and car storage;
- Direct discharge to the onsite sewer line;
- Several fires;
- Undocumented fill placement;
- Scrap metal storage; and
- Incidental spills and materials handling activities.

Contaminant sources at the Whitney property are largely related to drum and tank recycling and reconditioning activities conducted between approximately 1950 and 1985. The building contained a wash room with a floor drain connecting to the municipal sewer from the rear of the building (northern end of the building), a spray booth for painting of drums, and chemical storage areas.

As described in Section 2.1, the drain line connecting the former Whitney drum storage area to the municipal sewer system was investigated to determine the integrity of the drain line, surrounding soil characteristics and potential contaminant impacts. During the investigation activities, field PID screening indicated significant VOC concentrations within 15 feet of the exposed sewer pipe ranging from approximately 1,340 ppmv to over 9,999 ppmv. Recent well gauging data has indicated the presence LNAPL (measurable thickness of 0.08 feet in October 2011) and "thick globules of a petroleum-like product" (July 2013) in shallow monitoring well WB-201S, located to the rear of the building and proximate to the drain line (Figure 2-1 and Table 1-2).

Drum contents were also reportedly dumped directly into the municipal sewer prior to cleaning activities within the wash basin, which also drained to the municipal sewer. In 1978, a portion of

the contents of a tanker truck were discharged directly to the sewer manhole located in the northwest corner of the property.

The Whitney property has also been subject to several fires thought to be related to the contents of drums, significant vehicle and scrap metal storage, various smaller scale spills and poor chemical handling procedures. A series of at least eight fires reportedly occurred at the property between 1960 and 1986, the most destructive of which occurred in 1977 and 1979 (RETEC, 2003). The 1977 and 1979 fires reportedly destroyed the wooden "raw warehouse" building attached to the northern end of the main building and nearly destroyed the entire main building, respectively (RETEC, 2003). The wooden structure destroyed in 1977 was approximately 100-feet long by 40-feet wide and was never rebuilt (RETEC, 2003). Barrels awaiting refurbishment reportedly exploded during these fires as well (RETEC, 2003).

Murphy Property

The Murphy property lies to the west of the Whitney property and to the east of the commuter rail line (a.k.a., B&M Railroad). The property was used for storage of virgin and waste oil beginning in the 1920s. The property is predominantly covered by fill and bordered to the north and west by a wetland area. The property is currently operated by CHES as a waste oil handling and transfer facility, with their offices located on the adjacent 250 Salem Street property. Environmental investigation activities conducted by the EPA and property operators have identified several know or potential sources of contamination. These include the following:

- Former "oil yard" in northern portion of property;
- Former "oil pit" within central portion of property (beneath the current oil storage facility);
- Waste oil spreading for dust suppression;
- Periodic flooding; and
- Various minor operation related spills.

The northern portion of the property contained the "oil yard" that housed approximately twenty above-ground storage tanks (ASTs) for oil storage. The ASTs were surrounded by a two foot

high concrete secondary containment dike. The tanks have since been removed from this area leaving only the containment dike structure, presently overgrown with vegetation.

The central portion of the property contained a large depression known as the "oil pit" where waste oil and filters were disposed. Prior to CHES taking over operation of the property, this area underwent an environmental investigation and approximately 1,100 cubic yards of impacted soil material was removed; however, impacted material is believed to remain. The current oil storage facility was constructed over the former "oil pit" area. LNAPL was discovered on-site and thought to be associated with the former "oil yard" and "oil pit" activities.

Prior to 1979, waste oil was regularly spread on traveled portions of property for dust suppression. In addition, several known releases of fuel oil and waste oil have occurred at the property.

Murphy Wetland

The Murphy property is located adjacent to a wetland which is known to contain contaminant impacts related to previous activities at the Murphy property and adjacent properties. The Murphy Wetland is located between the upland portions of the Murphy, Whitney, Wildwood and Aberjona properties. Given the location of the former "oil yard" and "oil pit" at the Murphy property and former barrel washing activities at the Whitney property, historic site activities have the potential to have impacted the Murphy Wetland. Ongoing IRA activities being conducted at the Murphy property related to LNAPL associated with the former "oil yard" and "oil pit" also have the potential to impact the wetlands.

In addition, the wetland likely has impacts from releases originating from neighboring properties including the J.J. Riley Tannery to the west, and Wildwood property to the north, and by flooding.

J.J. Riley Tannery - A City of Woburn sanitary sewer easement, originating within the J.J. Riley Tannery property, crosses the northern portion of the Murphy property in the Murphy Wetland.

Historic overflow of the sanitary sewer manhole within the Murphy Wetland had the potential to contribute metals (e.g., total and hexavalent chromium) contamination to the wetland. A drainage swale originating at the J.J. Riley Tannery property discharges to the B&M Railroad property west of Murphy. A culvert discharges intermittent water from the drainage swale to the Murphy Wetland. The drainage swale, which was recently subject to a removal action under oversight by the EPA, and associated culvert has also potentially contributed metals (e.g., total and hexavalent chromium) contamination to the Murphy Wetland (EPA, 2004 and 2006).

In addition, the hillside adjacent to the drainage swale potentially resulted in the relocation of contaminants to the Murphy Wetland via erosion and downstream migration. As indicated in the MCP Phase II and Phase III report completed by TetraTech, Incorporated for the former J.J. Riley Site, prior waste management activities included dumping of tannery-related and solid wastes at the site and these wastes have been observed upon the hillside adjacent to the drainage swale (TetraTech, 2009). Total arsenic, cadmium, chromium, lead and mercury impacts were consistently detected in soil samples, along with less frequently detected PAHs and petroleum hydrocarbons (TetraTech, 2009). Arsenic, chromium and lead were detected within hillside samples at concentrations as high as 195 mg/kg, 39,500 mg/kg and 18,700 mg/kg, respectively. Metals (i.e., arsenic, chromium and lead) and less frequently PAHs and petroleum hydrocarbons impacts have also been detected downgradient of the hillside, indicating source migration (TetraTech, 2009).

Wildwood - One of five specific contaminated media identified in the ROD and Consent Decree for the Wells G&H Site that required remediation at the Wildwood property were mixed-contaminated soils. Mixed-contaminated soils are defined in the ROD as soils impacted with total cPAHs, PCBs, chlordane, 4,4'-DDT and/or lead. As described in the 100-Percent Design Report Mixed-Contaminated Soils (RETEC, 1994), excavation and remediation of mixed-contaminated soils targeted four distinct areas, including one area (i.e., "Area 4") located near the southern limit of the Wildwood property and adjacent to the northwest portion of the Murphy Wetland. Concentrations of cPAHs, PCBs, chlordane and lead were detected in samples collected from Area 4 in excess of ROD cleanup goals (RETEC, 1992). Given the location of

Area 4 relative to the Murphy Wetland, the potential exists for pre-remediation surface erosion to have impacted wetland sediments.

Flood Events - A significant portion of the Southwest Properties, including the Murphy property, are subject to flooding. Period flooding events have the potential to redistribute contamination from the wetland to the adjacent properties (e.g., relocation of metals impacts related to the former adjacent tannery) and introduce impacts to the wetland (e.g., hydraulic oil release from Whitney property during flooding in 1996).

Unremediated LNAPL - As discussed in documentation related to ongoing IRA activities being conducted by CHES under MassDEP RTN 3-22144, LNAPL related to the former disposal activities at the Murphy property has the potential to impact the wetlands. Separate-phase product was initially detected in monitoring wells in the vicinity of the former "oil yard" and "oil pit" (MW-7, MW-16 and MR-2SS) in November 2001. Subsequent IRA activities have included assessment, monitoring and product recovery. Additional IRA investigation activities have focused on the area surrounding MW-16 and an oil-sheen has been observed on wetland surface water adjacent to monitoring well MW-16.

Samples of the separate-phase product were collected from monitoring wells (i.e., MW-7 and MW-16) at the Murphy property as part of IRA investigation activities in 2002 (CHES, 2002). The product samples were analyzed for PCBs and total petroleum hydrocarbons and the detected concentrations of PCBs and TPH ranged from 3.7 mg/kg to 19 mg/kg and 500,000 mg/kg to 610,000 mg/kg, respectively (CHES, 2002). The sampled product from each well exhibited similar chromatogram signatures and was noted as most closely resembling the laboratory lubricating oil reference standard (CHES, 2002).

Additional separate-phase product sample collection and analysis was recently implemented by AECOM as part of the Southwest Properties investigation activities in December 2012 (see Appendix E.2). Samples of separate-phase product were collected for monitoring wells MW-16, MW-24 and MW-25. The samples were submitted for laboratory VOCs, EPH, VPH, TPH, total PCB and/or dioxin-like PCB congener analysis. Select VPH and EPH fractions, BTEX

compounds, naphthalene and VOCs (i.e., cis-1,2-dichloroethene, 1,2,4-trimethylbenzene and 1,3,5-trimethylbenzene) were detected in the samples from monitoring wells MW-16 and MW-24. TPH ranged from 300,000 mg/kg to 320,000 mg/kg, with C11-C22 aromatics ranging from 84,200 mg/kg to 61,300 mg/kg in monitoring wells MW-16 and MW-24, respectively. Total PCBs ranged in concentration from 77 mg/kg to 285 mg/kg and PCB TEQ concentrations ranged from 3.5E-03 mg/kg to 5.2E-04 mg/kg in wells MW-16, MW-24 and MW-25. The product was found to most closely resemble the laboratory reference standard for motor oil. Both the 2002 and 2012 product sampling analytical results indicate that LNAPL present within the Murphy property associated with the former "oil yard" and "oil pit" have potentially contributed to the Murphy Wetland sediment impacts.

2.5.2 Nature and Extent

Analytical data have been obtained from several environmental investigations encompassing the Southwest Properties and have included samples collected from surface soil/subsurface soil, sediment, groundwater, surface water, subslab soil gas and indoor air. A detailed discussion of analytical results associated with previous investigations is provided in the RI and Supplemental RI prepared by RETEC, the HHRA/ERA (EPA, 2006), and the CARP and ongoing IRA documentation prepared by CHES for the Murphy property. Supplemental environmental sampling was conducted by AECOM in 2010/2011/2013 toward addressing data gaps identified by EPA in its May 14, 2009 draft comment letter on the 2003 Supplemental RI for the Southwest Properties. Soil, groundwater, surface water, sediment, subslab soil gas and indoor air sampling points investigated to date are depicted in Figure 2-1.

The discussion of the nature of Site impacts is based on the identification of various activities and uses at each property. As previously noted, contaminants of potential concern at the Site include VOCs, PAHs, pesticides, PCBs, dioxin-like PCB congeners, petroleum hydrocarbons and metals. Based on previous laboratory analytical results, the following provides a summary of the site-specific contaminant impacts by media. Analytical results generally indicate impacts are consistent with the historic use of each property. However, select media within portions of the Site may be influenced by external factors independent of specific historic property usage.

Surface Soil / Subsurface Soil

This discussion of the nature of soil impacts includes the generalized surface soil horizon and deeper subsurface impacts. Both surface soils and subsurface soils are largely impacted by previous Site activities and include elevated detections of VOCs, PAHs, pesticides, PCBs, dioxin-like PCB congeners, petroleum hydrocarbons and metals when compared to applicable EPA screening or potentially applicable cleanup criteria.

VOCs - Historic detection of VOCs in surface soils have generally been low concentration and proximate to the barrel washing area to the rear of the Whitney property (i.e., vicinity of WB-201 and WB-202 sample locations) and to the Murphy oil yard area (i.e., vicinity of sample locations MR-SS2 and MR-202) where known historic operational and disposal activities took place. Detections generally consisted of chlorinated VOCs (e.g., TCE, PCE, cis-1,2-dichloroethene) throughout the Site in both surface and subsurface soils. Elevated concentrations of VOCs in subsurface soils were largely detected in association with the barrel washing area and floor drain beneath the Whitney property building, which is known to have discharged to the sewer by a drain line. During initial excavations near the rear of the Whitney building in December 2010 to uncover the sewer pipe, the field PID instrument recorded elevated VOC concentrations within 15 feet of the exposed sewer pipe ranging from approximately 1,340 ppmv to over 9,999 ppmv (Appendix E.1).

PCBs/Pesticides - The highest concentrations of pesticides (aldrin, alpha-BHC, chlordanes, lindane, heptachlor and heptachlor epoxide), PCBs and dioxin-like PCB congeners in surface and subsurface soils were also generally detected to the rear of the former barrel washing area at the rear of the Whitney property (e.g., vicinity of sample locations WB-7D, WB-10D and WB-203). The area was noted by RETEC in the Supplemental RI as a soil “hot spot” for alpha- and gamma-chlordane. Elevated concentrations of PCBs and dioxin-like PCB congeners were widespread in surface and subsurface soils throughout the rear and southern portions of the Whitney property, particularly in the vicinity of the former barrel washing operations. In association with more recent Supplemental RI activities, elevated concentrations of PCBs (in excess of 100 mg/kg) were detected near the sewer line extending north from the rear of the

Whitney building. PCBs have largely been absent from surface and subsurface soil samples collected from the Aberjona property, with the exception of one surface soil location (AB-SS4) sampled prior to construction of the ice skating rink and one subsurface sample location (AB-SS8D) in the northern portion of the former salvage yard.

Additional contaminants of concern such as PAHs, petroleum, and metals tend to be more widely distributed in surface and subsurface soils throughout the Site, as noted below.

PAHs and Petroleum - Elevated concentrations of PAHs (e.g., benzo(a)anthracene and benzo(a)pyrene) have been detected in surface soils throughout the Murphy property, Whitney property and the rear of the Aberjona property (former salvage yard area). Elevated concentrations of PAHs in subsurface soils were encountered throughout the Whitney property. These detections are consistent with past operational activities including storage within the "oil yard" and dust suppression activities at the Murphy property, discharges during barrel washing activities at the Whitney property and operation of the Aberjona salvage yard. Concentrations of Total Petroleum Hydrocarbons (TPH) have tended to be highest in surface and subsurface soils in the vicinity of the "oil yard" at the Murphy property and former barrel washing portion of the Whitney property. Petroleum hydrocarbons also tend to be present within the Aberjona property in surface and subsurface soils, attributable to former salvage yard operations.

Metals - The presence of metals (e.g., arsenic, cadmium, cobalt, chromium and lead) in surface and subsurface soils is common throughout the Southwest properties. Thallium was also detected at elevated concentrations at a small number of locations in surface and subsurface soil at the Murphy property. Large portions of each of the properties has been subject to filling activities (i.e., up to 5-feet at the Aberjona and Whitney properties and up to 12-feet at the Murphy property), which may be associated with the widespread distribution of metals. Portions of each of the properties are also subject to flooding, which could result in redistribution of off-site and on-site sources of metals within the Southwest Properties. Concentrations of metals in excess of applicable regulatory standards (i.e., EPA RSLs and MCP Method 1 S-1 soil standards) have also been detected in association with past Site activities such as the "oil yard" at the Murphy property, Whitney barrel washing operations and Aberjona salvage yard operations.

Focused investigation of metals associated with overflows of the sanitary sewer manhole to the rear of Murphy property has also indicated the presence of total chromium, hexavalent chromium and lead. Hexavalent chromium is not ubiquitous throughout the Site, but tends to correlate to the areas of highest total chromium detections. Hexavalent chromium, as well as arsenic, are primary contributors to risk in surface and subsurface soils at the Whitney property.

Thallium is not ubiquitous throughout the Site, but tends to correlate with areas of elevated metals detections including arsenic, cobalt, iron and manganese. Thallium has historically been manufactured for use in optics (lenses, prisms and windows for infrared detection and transmission equipment), electronics (e.g., photoresistors, photoelectric cells, semiconductors, etc.), thallium salts are also added to fluorescent materials as activators, medical applications as a radioisotope and as a rodenticide and ant killer prior to 1972.

Sediment (Murphy Wetland)

The Murphy Wetland, located between the upland portions of the Murphy, Whitney, Wildwood and Aberjona properties, is subject to potential impacts from both past activities at the Southwest Properties, as well as the potential influence of off-site contaminants. As a result elevated concentrations of PAHs, pesticides, PCBs, dioxin-like PCB congeners and metals (arsenic, cadmium, chromium and lead) have been historically detected within Murphy Wetland sediment samples. The wetland was noted by RETEC in the Supplemental RI as a sediment “hot spot” for total chromium. In addition, elevated concentrations of lead (ranging from 12,000 to 35,100 mg/kg) have been detected in sediment samples MR-11, P-12, P-14 and SW-2 located within the wetland adjacent to two monitoring wells (MW-16 and MW-24) where LNAPL related to the former Murphy “oil yard” and “oil pit” is present. As noted in the CARP (1996), the distribution of lead impacts in this area appears to correlate with the distribution of TPH impacts and originate from the former tank area in the northern portion of the property. Elevated lead has also been detected at sediment sample P-43 (11,100 mg/kg), located north of the former ”oil yard” area. LNAPL samples analyzed to data indicate elevated concentrations of VOCs, TPH, EPH, VPH, total PCBs and PCB TEQ that may have potentially contributed to wetland impacts. To

date, LNAPL samples have not been analyzed for metals, though it may also be a source of lead impacts to the wetland.

The historic wetland sediment sampling has indicated a widespread distribution of chemical impacts. The Murphy Wetland is located adjacent to the former Murphy "oil yard," and the Whitney property. The wetland is also subject to the influence of other known and suspected releases including impacts originating from the J.J. Riley Tannery property and Wildwood property. For example, the J.J. Riley Tannery property to the west has likely contributed historic chromium contamination to the Murphy Wetland sediments as a result of sanitary sewer manhole overflows (EPA, 2004 and 2006). In addition, the migration of tannery-related and solid waste impacts from the hillside, adjacent drainage swale and associated culvert potential contributed metal impacts (e.g., arsenic, cadmium, chromium and lead), and to a lesser degree PAHs and petroleum hydrocarbon impacts, to the Murphy Wetland (EPA, 2004 and 2006 and TetraTech, 2009). The wetland is subject to flooding which has the potential to provide input and redistribution of wetland sediment impacts.

The potential for the migration of impacted material from the southern portion of the Wildwood property to the Murphy Wetland also exists. Mixed-contaminated soils located adjacent to the northeastern portion of the Murphy Wetland exhibited concentrations of cPAHs, PCBs, chlordane and lead in excess of ROD cleanup goals (RETEC, 1992).

The LNAPL related to the former Murphy "oil yard" (MW-16, MW-24 and MW-25) and "oil pit" (MW-7) areas also has the potential to impact wetland sediments. The LNAPL was sampled and analyzed from MW-16 and contained PCBs and TPHs (Aroclor 1260 at 19 ppm, TPHs at 610,000 ppm), while a groundwater sample contained C11-C22 Aromatics (at 2,500 µg/L). (Clean Harbors, 2002) Separate-phase product has also historically been observed within monitoring well MR-2SS (south of the former "oil yard" secondary containment dike). LNAPL samples collected in December 2012 from monitoring wells MW-16, MW-24 and MW-25 indicated TPH ranging from 300,000 mg/kg to 320,000 mg/kg, and C11-C22 Aromatics ranging from 61,300 mg/kg to 84,200 mg/kg. Total PCBs ranged in concentration from 77 mg/kg to 285 mg/kg and PCB TEQ concentrations ranged from 5.2E-04 mg/kg to 3.5E-03 mg/kg.

Groundwater

As previously discussed, the Southwest Properties are generally underlain by unconsolidated glacial deposits overlying bedrock. Groundwater beneath the Site generally flows across the Southwest Properties toward the Aberjona River and associated wetland areas. Groundwater flow is generally toward the east in both the unconsolidated soils and shallow bedrock. The depth to groundwater at the Southwest Properties varies, but generally ranges from 5 to 9 feet below ground surface. Locally, the groundwater table is influenced by river stage, principally at the Aberjona property.

Groundwater monitoring has indicated that the shallow overburden, deep overburden and shallow bedrock are largely impacted by the presence of chlorinated and non-chlorinated VOCs. The presence of VOCs such as BTEX compounds, cis-1,2-DCE, TCE, PCE and vinyl chloride have been detected in shallow groundwater throughout a significant portion of the Site. Detections of VOCs in the shallow overburden are likely related to past operational activities at each of the Southwest Properties, with definable areas of impact (e.g., Whitney barrel washing and drain line, Murphy "oil yard" and Aberjona auto repair area). Chlorinated VOCs (e.g., TCE and PCE) have also been detected in the deep overburden and shallow bedrock monitoring wells. Elevated concentrations of VOCs in deeper groundwater tend to be associated with the Whitney property and the Aberjona property. These VOCs are contaminant of concerns at the Whitney and Aberjona properties.

Detections of VOCs in groundwater at the Southwest Properties are also likely influenced, in part, by migration from separate upgradient sources (e.g., Wildwood property). As discussed in Section 1.5.3.2 (Southwest Properties Hydrogeology), an apparent transient mixing zone exists within the shallow groundwater along the boundary between the Southwest Properties and the Wildwood property. At times, shallow groundwater appears to originate from the Southwest Properties, as suggested by the detection of low concentrations of benzene in the shallow and intermediate overburden in monitoring wells BOW-16, BW-16R, S-77S and S-77D (GeoTrans, 1994). Benzene has also been detected in groundwater beneath the Southwest Properties, but not

in groundwater beneath the Wildwood property with the exception of BSW-2 and BW-2R (immediately adjacent to the Whitney property northern boundary).

At other times, shallow groundwater appears to originate from the Wildwood property and flow toward the northern boundary of the Southwest Properties. For example, historic concentrations of VOCs, such as TCE, have been detected in groundwater at elevated concentrations in monitoring well BW-5 (i.e., as high as 5,700 µg/L), which is located on the Wildwood property. Consistent with an evaluation of groundwater flow patterns in October 2011, concentrations of TCE in groundwater in excess of 100 µg/L have historically been detected in downgradient wells BSSW-16, BW-15 and S-77S. Concentrations of TCE of this magnitude have not been detected in groundwater in potential upgradient wells within the Southwest Properties.

As described in Section 1.5.3.2, recent monitoring well gauging data collected in October 2011 and July 2013 suggest that groundwater flow within deeper overburden and bedrock is dominated by movement from beneath the Wildwood property toward the northern portion of the Southwest Properties (i.e., BW-16 and S-77 well clusters). Recent groundwater analytical data collected in July 2013 support this flow pattern (Appendix E.5). For example, the highest concentrations of TCE detected within the shallow bedrock in July 2013 were in monitoring wells BW-17R (165 µg/L), WW-101SR (325 µg/L) and S-77SR (140 µg/L). This is consistent with the July 2013 groundwater level measurements, which indicate an easterly groundwater flow direction within the bedrock from the upgradient BW-17R and WW-101SR monitoring wells to monitoring well S-77R (Appendix E.5).

The presence of additional contaminants in groundwater throughout the Site, including PAHs, pesticides, PCBs, VPH, EPH and metals, tend to be limited to groundwater within the shallow overburden. Detection of VPH and EPH compounds tend to be observed in the vicinity of the former “oil yard” and “oil pit” at the Murphy property and former barrel washing area at the Whitney property. Total PCBs, TPH, EPH (including C11-C22 Aromatics) and VPH are also observed in LNAPL at the Murphy Property and, given the proximity of the LNAPL to the wetland and historic presence of a surface water sheen, have the potential to impact wetland surface water and sediments. Arsenic, lead and SVOCs tend to be detected in the vicinity of the

former “oil yard” at the Murphy property. The highest concentrations of lead have been detected in monitoring wells MW-16, MW-18S and MW-24 at the Murphy property, two of which (MW-16 and MW-24) historically have exhibited LNAPL and are located immediately adjacent to an area of elevated concentrations of lead in wetland sediments (sediment sample locations MR-11, P-12, P-14 and SW-2). Pesticides tend to be limited to the Whitney and Aberjona properties and PCBs have recently been detected in association with the former barrel washing area and sewer line to the rear of the Whitney property.

Surface Water

Samples of surface water were collected from the wetland on the Murphy property. At the request of the EPA, surface water samples were collected as part of the 2002 Supplemental RI activities to evaluate the presence of total and dissolved metals. Surface water within the Murphy Wetland has the potential to be impacted by both Southwest Properties and off-site sources.

An oil sheen has been observed on wetland surface water adjacent to monitoring well MW-16. The highest concentrations of lead have been detected in monitoring wells MW-16, MW-18S and MW-24 at the Murphy property, two of which (MW-16 and MW-24) historically have exhibited LNAPL and are located immediately adjacent to an area of elevated concentrations of lead in wetland sediments (sediment sample locations MR-11, P-12, P-14 and SW-2). The potential exists for contaminants in groundwater to discharge to surface water and impact wetland sediments.

Subslab Soil Gas

Recent investigation of subslab soil gas indicates the presence of VOCs and/or petroleum hydrocarbons related to past Site activities beneath structures at each of the Southwest Properties. A total of ten subslab soil gas points were installed during the 2010-2011 Supplemental RI to help identify sources beneath the commercial buildings and to provide a preliminary indication of the potential for vapor intrusion at each of the properties. VOCs and petroleum hydrocarbons were detected in the soil gas sample collected from the Murphy

property. VOCs were also detected in soil gas samples collected in association with the drain line at the Whitney property and the current office space at the Aberjona property. Petroleum hydrocarbons were detected in association with the garage and floor drain areas of the Aberjona property.

One additional subslab soil gas point was installed in 2013 to assess the potential vapor intrusion pathway at the existing Aberjona residence (Figure 2-3). The subslab soil gas point was installed in accordance with the *Vapor Intrusion Assessment Work Plan, Revision 2* (AECOM, 2013). The subslab soil gas point, located in a former finished portion of the basement, was sampled for VOCs and APH in April and August, 2013. Following leak testing of the sampling apparatus, the subslab soil gas samples were collected using SUMMA® canisters.

Subslab samples collected in April and August, 2013 exhibited APH compounds and VOCs, including C_5-C_8 aliphatics and several VOCs (i.e., 1,1,1-TCA, 1,2-DCA, chloroform, cis-1,2-DCE, Freon-113, PCE, trans-1,2-DCE and TCE) that have also been detected in shallow groundwater at the Southwest Properties.

Indoor Air

Two indoor air samples (plus one duplicate analysis) and one ambient air sample were collected from the existing Aberjona residence during each of two sampling rounds in April and August 2013. One sample was collected from the basement and one sample was collected from the first floor (kitchen area), with the ambient air sample collected from outside of the residential building (Figure 2-3). Each sample was collected using individually certified SUMMA® canisters in accordance with the *Vapor Intrusion Assessment Work Plan, Revision 2* (AECOM, 2013) and approved *Quality Assurance Project Plan* (QAPP; AECOM, 2010). Each sample was submitted for laboratory APH and VOC analysis.

Indoor air samples (basement and first floor) collected in April and August, 2013 exhibited detectable concentrations of both APH compounds (C_5-C_8 aliphatics) and VOCs. Several VOCs (i.e., chloroform, cis-1,2-DCE, Freon-113, PCE, trans-1,2-DCE and TCE) and C_5-C_8 aliphatics have also been detected in shallow groundwater at the Southwest Properties and subslab soil gas

samples collected from the existing Aberjona residence. Although several of these VOCs (i.e., chloroform, Freon-113, trans-1,2-DCE and/or TCE) were detected in the ambient air sample collected during each sampling event, the potential exists for a complete pathway for migration of contaminants to indoor air.

2.5.3 Fate & Transport

The following section provides a generalized discussion of the fate and transport of contaminants identified at the Site. This section summarizes environmental fate and transport characteristics of identified contaminants and discusses existing and potential migration pathways of contamination at the Site.

2.5.3.1 Environmental Fate and Transport Characteristics

Chemicals identified in Site soil, sediment, groundwater, surface water, subslab soil gas and/or indoor air include VOCs, PAHs, pesticides, PCBs, dioxin-like PCB congeners, petroleum hydrocarbons and metals based on subsurface investigations performed by the EPA and property operators during previous environmental investigations. The distribution of chemical impacts is influenced, in part, by factors such as the physical and chemical properties of the chemicals, geochemical reactions, the nature and location of sources, and Site characteristics such as geology, hydrology, and topography. Characteristics of these compounds that influence fate and transport processes and affect migration include:

- Specific Gravity;
- Water Solubility;
- Vapor Pressure;
- Henry's Law Constant;
- Organic Carbon Partition Coefficient (K_{oc}); and
- Log Octanol/Water Partition Coefficient (Log K_{ow}).

The majority of the chemicals detected at the Southwest Properties include various contaminants (chlorinated VOCs, EPH compounds, PAHs, PCBs, dioxin-like PCB congeners and metals) with

specific gravities greater than 1. Contaminant groups such as PAHs, PCBs and metals also generally exhibit a relatively low level of water solubility, low vapor pressure and low volatility. Impacts such as PAHs and PCBs tend to exhibit relatively high K_{oc} values (high sorption potential and limited potential to leach) and K_{ow} values (tendency to bind to soil). Metals tend to be less likely to bind to soil and have a higher potential to leach into groundwater.

Additional contaminant groups (non-chlorinated VOCs and select petroleum hydrocarbons) tend to exhibit specific gravities less than 1. These contaminant groups exhibit a range of solubility from low (e.g., high molecular weight hydrocarbons) to relatively high (e.g., BTEX compounds), and tend to exhibit higher vapor pressures and higher relative volatility when compared to the PAHs, PCBs and metals. These contaminant groups tend to exhibit low K_{oc} values, indicating a high potential to leach, and are compounds are more likely to bind to soil based on the log K_{ow} values.

Note that cosolvency is also an issue, particularly at Murphy where the petroleum LNAPL contains within it higher molecular weight compounds with greater density such as PCBs, thus altering typical fate and transport expectations.

2.5.3.2 Migration Pathways

Figure 2-2 presents a schematic conceptual site model that illustrates, on a site-specific basis, how contaminants entered the environment, how the contaminants were likely transported at the Site, and the potential for exposure to human and environmental receptors, as currently supported by the available data, information on contaminants identified at the Site, and contaminants properties. An analysis of the potential migration pathways as they relate to the contaminants identified at the Site is presented in the following sections**.**

Soil

Contaminants detected at the Site above applicable screening criteria include VOCs, PAHs, pesticides, PCBs, dioxin-like PCB congeners, petroleum hydrocarbons and metals. Soil impacts throughout the Site are generally believed to be associated with direct placement/discharge associated with historic site activities. Contaminants of concern such as PAHs, pesticides, PCBs, higher molecular weight hydrocarbons and metals tend to exhibit strong partitioning tendencies and limited potential to leach, and/or low solubility and have low likelihood of migrating with groundwater and leaching through the soil. These chemicals of concern are also highly persistent (do not readily degrade) and contaminants like PCBs have bioaccumulation properties.

Contaminant compounds such as VOCs and VPH are relatively more soluble and mobile and therefore have a higher likelihood of leaching through the soil and migrating to groundwater.

The northern portion of the Southwest Properties is bordered by wetlands, including the Murphy Wetland, and by the Aberjona River along the eastern boundary (adjacent to the Aberjona property). The highest topographic elevations within the Site are located in the southern portion of the Murphy property. Although portions of the Site topography are relatively flat, given the prevalence of nearby surface water bodies, the potential for transport of contaminated soil via surface water runoff, erosion and fugitive dust to wetland sediment and surface water is high. The drain culvert and potential for historic sewer overflows to the rear of the Murphy property also represents a potential migration pathway for soil impacts to wetland sediment and surface water.

Significant portions of the Site are also subject to periodic flooding events. These events have the potential to redistribute contamination from the wetland to the adjacent properties (e.g., relocation of metals impacts related to the former adjacent tannery) in addition to introduction of impacts to the wetland.

Future development of the Site or future maintenance activities could disturb soils or involve soil handling making these soils available for fugitive dust transport and stormwater runoff if

appropriate engineering controls and work practices are not implemented during activities that could disturb the soil.

Sediment

Elevated concentrations of PAHs, pesticides, PCBs, dioxin-like PCB congeners and metals (arsenic, cadmium, chromium and lead) have historically been detected within Murphy Wetland sediment samples. As previously noted, runoff and erosion from portions of the Southwest Properties has likely contributed to the presence of these contaminants in the sediment, including a localized area of elevated lead concentrations east of the former waste oil AST area. In addition, redistribution of contaminants from adjacent disposal sites (e.g., metals impacts related to the former J.J. Riley Tannery and mixed-contaminated soil impacts from the Wildwood property) have also likely impacted the Murphy Wetland. Impacts from hillside waste disposal activities and the adjacent drainage swale and associated culvert, conveying runoff from the adjacent railroad tracks and nearby former J.J. Riley Tannery, is associated with impacts to the wetland sediments, particularly metals such as arsenic, cadmium, chromium and lead. In addition, historic overflows of the sanitary sewer manhole, located in the western portion of the Murphy property and originating from the J.J. Riley Tannery property, are likely to contribute impacts to wetland sediments via runoff. Potential redistribution of cPAHs, PCBs, chlordane and lead impacted soil material from the Wildwood property has also possibly impacted the Murphy Wetland.

Significant portions of the Site are also subject to periodic flooding events. These events have the potential to redistribute contamination from the wetland to the adjacent properties (e.g., relocation of metals impacts related to the former adjacent tannery) in addition to introduction of impacts to the wetland.

LNAPL related to the former disposal activities at the Murphy property has the potential to impact wetland sediment. Separate-phase product was initially detected in monitoring wells in the vicinity of the former “oil yard” and “oil pit” (MW-7, MW-16 and MR-2SS). Subsequent IRA investigation activities have focused on the area surrounding MW-16, immediately adjacent

the wetland, and an oil sheen has been observed on wetland surface water adjacent to monitoring well MW-16. Laboratory analytical analysis of the separate-phase product has indicated the presence of select VOCs, PCB, VPH and EPH fractions, BTEX compounds and naphthalene. In addition, elevated concentrations of lead have been detected in monitoring wells MW-16 and MW-24, located immediately adjacent to an area of elevated concentrations of lead in wetland sediments including sample locations MR-11, P-12, P-14 and SW-2. It is likely that separate-phase product has impacted the wetland sediments via discharges to surface water given the proximity of the monitoring wells historically exhibiting LNAPL to the wetland and past presence of a surface water sheen.

Shallow groundwater from portions of the Southwest Properties also has the potential to impact wetland sediment. Shallow groundwater adjacent to the wetlands contains PCBs, PAH, VPH, EPH and metals and portions of the shallow groundwater may migrate to the Murphy Wetland.

Groundwater

With the exception of select chlorinated VOCs, the presence of contaminants in groundwater throughout the Site, including PAHs, pesticides, PCBs, petroleum hydrocarbons and metals, tend to be limited to groundwater within the shallow overburden. These contaminants tend to be highly persistent in the environment and generally exhibit relatively low solubility. The detections of these contaminants in the shallow groundwater tend to be localized in portions of the Site subject to historic operations (e.g., Murphy “oil yard” and “oil pit”, and former Whitney barrel washing areas). This is consistent with the physical and chemical properties of the contaminants (e.g., relative insolubility and high sorption potential) and site-specific shallow subsurface characteristics which would limit migration within the shallow groundwater. Characterization of deep overburden and bedrock groundwater quality is presently limited.

The presence of VOCs such as BTEX compounds, cis-1,2-DCE, TCE, PCE and vinyl chloride have been detected in shallow groundwater throughout a significant portion of the Site. Detections of VOCs in the shallow overburden are likely related to past operational activities at each of the Southwest Properties, with definable areas of impact (e.g., Whitney barrel washing

area, Murphy “oil yard” and Aberjona auto repair area). Due to the resistance to degradation and properties as dense non-aqueous phase liquids, select chlorinated VOCs (e.g., TCE and PCE) have also been detected in the deep overburden and shallow bedrock groundwater. The detections of VOCs in deeper groundwater tend to be associated with the Whitney property and the Aberjona property. These VOCs are a contaminant of concerns at the Whitney and Aberjona properties.

Detections of VOCs are also likely associated, in part, to migration from additional upgradient sources (e.g., Wildwood Property). As discussed in Section 1.5.3.2, an apparent transient mixing zone exists within the shallow groundwater along the boundary between the Southwest Properties and the Wildwood property. At times shallow groundwater appears to originate from the Southwest Properties, as suggested by detection of low concentrations of benzene in the shallow and intermediate overburden in monitoring wells BOW-16, BW-16R, S-77S and S-77D (GeoTrans, 1994). Benzene has been detected in groundwater beneath the Southwest Properties, but has not been detected in monitoring wells installed in portions of the Wildwood property that are not proximate to the Southwest Properties.

At other times shallow groundwater appears to originate from the Wildwood property. Historic concentrations of VOCs, such as TCE, have been detected in groundwater at elevated concentrations in monitoring well BW-5 (i.e., as high as 5,700 µg/L) located on the Wildwood property. Consistent with groundwater flow patterns in October 2011, concentrations of TCE above 100 µg/L have historically been detected in groundwater in downgradient monitoring wells BSSW-16, BW-15 and S-77S, while TCE concentrations of this magnitude are largely absent in groundwater monitoring wells installed at the Southwest Properties.

Recent monitoring well gauging data collected in October 2011 and July 2013 indicate that groundwater within the deeper overburden and bedrock tends to flow from beneath the Wildwood property toward the northern portion of the Southwest Properties (i.e., BW-16 and S-77 well clusters). Groundwater analytical data collected in July 2013 also appear to support this pattern (Appendix E.5). For example, the highest concentrations of TCE within the shallow bedrock in July 2013 were detected in monitoring wells BW-17R (165 µg/L), WW-101SR (325

µg/L) and S-77SR (140 µg/L). This is consistent with the July 2013 groundwater level measurements, which indicate an easterly groundwater flow direction within the bedrock from the upgradient BW-17R and WW-101SR wells to S-77R (Appendix E.5).

The recent detection of LNAPL, likely related to the former Murphy "oil yard" (montoring wells MW-16, MW-24 and MW-25) and "oil pit" (monitoring wells MW-7 and MR-206 [sheen]) areas, adjacent to the Murphy Wetland and associated migration of contaminants such as VOCs, PCBs, petroleum hydrocarbons and metals also has the potential to impact wetland sediments. Elevated concentrations of lead (ranging from 11,000 to 35,100 mg/kg) have been detected in sediment samples MR-11, P-12, P-14 and SW-2 located within the wetland adjacent to monitoring wells MW-16 and MW-24 where LNAPL related to the former Murphy "oil yard" and "oil pit" is present. As noted in the CARP (1996), the distribution of lead impacts in this area appears to correlate with the distribution of TPH impacts and originate from the former tank area in the northern portion of the property.

Recent well gauging data has also indicated the presence LNAPL (measurable thickness of 0.08 feet in October 2011) and "thick globules of a petroleum-like product" (July 2013) in shallow monitoring well WB-201S, located to the rear of the building and proximate to the drain line (Table 1-2) on the Whitney property. The recent detection of LNAPL, like related to former operations (e.g., drum cleaning, use of floor drains, etc.) at the Whitney property, adjacent to the wetland has the potential to impact wetland sediments.

Surface Water

As previous noted significant portions of the Site are also subject to periodic flooding events. These events have the potential to redistribute contamination, particularly metals, from the wetland to the adjacent properties in addition to introduction of impacts to the wetland.

IRA activities in association with the presence of LNAPL in the vicinity of the former "oil yard" and "oil pit" are ongoing. As noted in IRA-related documents submitted to the MassDEP, an oil sheen has been observed on wetland surface water adjacent to monitoring well MW-16. This has

the potential to impact surface water with known LNAPL-related contaminants such as PCBs and petroleum hydrocarbons.

Subslab Soil Gas and/or Indoor Air

Recent investigation of subslab soil gas indicated the presence of VOCs and/or petroleum hydrocarbons beneath structures at each of the Southwest Properties. The presence of contaminants in subslab soil gas samples correlates with historic Site activities (e.g., Whitney barrel washing and drain line, Murphy "oil yard" and "oil pit", and Aberjona auto repair area) and indicates the potential for VOCs to impact indoor air at each of the properties via vapor intrusion.

In addition, recent subslab soil gas and indoor investigation activities at the existing Aberjona residence indicate the presence of APH (C_5-C_8 aliphatics) and several VOCs (i.e., chloroform, cis-1,2-DCE, Freon-113, PCE, trans-1,2-DCE and TCE) that have also been detected in shallow groundwater at the Southwest Properties and subslab soil gas samples collected from the existing Aberjona residence. The presence of these contaminants in both subslab soil gas and indoor air samples (basement and first floor) are consistent with historic Site activities at the Southwest Properties, particularly the Aberjona property, and although several of the VOCs (i.e., chloroform, Freon-113, trans-1,2-DCE and/or TCE) were detected in the ambient air sample collected during each sampling event, the potential exists for a complete pathway for migration of contaminants to indoor air.

Food Chain

With the exception of the Murphy Wetland located between the upland portions of the Murphy, Whitney, Wildwood and Aberjona properties, no other significant wildlife habitat exists on the Site. The remaining portions of the Southwest Properties generally consist of occupied buildings, storage areas and pavement/barren dirt areas. The Murphy Wetland contains areas of forested/scrub-shrub wetland and a seasonally ponded area.

Historic activities at the Site may have resulted in contamination of the adjacent Murphy Wetland sediments and surface water. These contaminants may directly affect aquatic organisms including invertebrates and amphibian larvae and/or may be transferred to aquatic vegetation or macroinvertebrates. The plants and invertebrates may subsequently be consumed by ecological receptors inhabiting the wetland potentially resulting in adverse impacts to these populations or to higher trophic levels.

3.0 BASELINE HUMAN HEALTH RISK ASSESSMENT

3.1 Introduction

In 2006, EPA finalized a baseline risk assessment for the Southwest Properties in Woburn, Massachusetts, based on soil, groundwater, sediment and surface water data collected through 2002. This section of the report contains an updated baseline human health risk assessment for the Southwest Properties, incorporating supplemental soil, groundwater, subslab soil gas and indoor air data collected in 2010, 2011 and/or 2013, and the most current risk assessment methodology and toxicity information. Monitoring wells BSW-2, BW-2R, BOW-16, BSSW-16, BW-16R, and the S77 well cluster are located on the Wildwood property. Due to their close proximity to the Southwest Properties, the chemical data obtained from have been included in the risk assessment. Though no surface water and sediment data were collected in 2010/2011/2013 as part of the supplemental investigation, the Murphy Wetland has been included in this update to incorporate methodological and toxicological changes.

The focus of this risk assessment is the quantitative, and in some cases qualitative, evaluation of potential risks to human receptors who have the potential for current and/or future exposure to contaminants in soil, groundwater, indoor air, sediment and surface water. All three Southwest Properties are active commercial properties, one of which includes a residence (the existing Aberjona residence) which is evaluated for potential indoor air impacts associated with shallow groundwater contamination via the vapor intrusion pathway[5]. Portions of each of the properties are paved. A wetland area is found between the upland portions of the Murphy, Whitney, Wildwood and Aberjona properties (i.e., the Murphy Wetland).

The Aberjona property includes a residence. However, soils in the backyard of this residence as well as sediment and surface water at the Aberjona property were evaluated as part of the Wells G&H Operable Unit 3 (OU-3) risk assessment (EPA, 2004a), which can be found in EPA's Draft Final MSGRP RI Report (EPA, 2005a). As part of the evaluation, surficial sediment and

[5] Vapor intrusion is defined as the movement of VOCs from groundwater into soil gas and then into a building. Only VOCs present in indoor air as part of a complete vapor intrusion pathway are evaluated in the risk assessment.

floodplain soil samples were collected from the backyard of the existing Aberjona residence, adjacent to the Aberjona River, and analyzed for VOCs, PAHs, PCBs and/or metals. Soils and sediments were evaluated for young child and adult exposures, assuming dermal contact and incidental ingestion with impacted media for 104 days per year for 30 years. Risks and hazards were estimated to be within or below EPA risk management guidelines. Therefore, no further evaluation of the residential portion of the Aberjona property was conducted as part of this investigation, except for the collection of subslab soil gas and indoor air data at the existing Aberjona residence to assess the vapor intrusion pathway associated with the migration of VOCs from shallow groundwater. Additional details related to the soil and sediment evaluation at the existing Aberjona residence can be found in the 2004 risk assessment (EPA, 2004a and 2005a).

3.1.1 Purpose and Scope

The purposes of the baseline human health risk assessment are: 1) to evaluate the potential human health risks that may be posed by chemical contamination of the soil, groundwater, indoor air, surface water, and sediment within currently accessible and future potentially accessible portions of the Site; and 2) to provide a basis for decisions as to whether remedial action is necessary. This baseline risk assessment may also be used qualitatively to identify site conditions (chemicals, exposure pathways, locations) of greatest potential concern.

According to EPA guidelines (EPA, 1989), the baseline risk assessment generally consists of four basic steps summarized below:

- **Hazard Identification.** Determination of the nature and amount of chemicals that could potentially be encountered at a site, and selection of those chemicals that are of potential concern for the assessment of the impact on human health.

- **Exposure Assessment.** Quantification of the extent, frequency, and duration of actual or potential exposure to chemicals by pathways relevant to a site and the activities of potential receptors.

- **Toxicity Assessment.** Identification of the types of health effects that could be associated with exposure to these chemicals, determination of the relationship between exposure (dose) and the probability of occurrence of the health impact (response).

- **Risk Characterization.** Estimation of the probability that an adverse health impact may occur as a result of exposure to chemicals in the amount and by the pathways identified and the uncertainty in those estimates.

The baseline human health risk assessment for the Site was conducted using methodologies required by EPA guidelines (EPA, 1989; 1991a; 1991c; 1992; 2001; 2004b; 2005b; 2010; 2011b). A baseline risk assessment is intended to be site-specific; therefore, site-specific information was incorporated into the evaluation whenever available. In the absence of site-specific information, default assumptions, as specified by EPA guidance, or professional judgment were used.

The baseline human health risk assessment provides estimates of risk, under both current use and hypothetical future use scenarios, to both the central tendency exposure (CTE) receptor and the reasonable maximum exposure (RME) receptor. The CTE receptor is used to represent average exposures occurring at an exposure point while the RME receptor is used to represent the high-end (upper-bound) exposure that is reasonably expected to occur at an exposure point. Exposure pathways and exposure routes are selected based on current and future land use. Exposure assessments model human exposure by these pathways according to algorithms in relevant guidelines. Variables contributing the most to estimates of risk or to the uncertainty in the risk assessment have been identified. Each of these steps is discussed in more detail in the appropriate sections of the report.

This baseline human health risk assessment consists of several sections. Subsection 3.1.2 identifies current and future exposure points and receptors. Section 3.2, Hazard Identification, describes the environmental samples used for the risk assessment, the selection of chemicals of potential concern (COPCs) from among the chemicals identified at the Site, and the determination of Exposure Point Concentrations (EPCs). Section 3.3, Exposure Assessment,

describes the selection of receptors and exposure pathways to be evaluated and the calculation of dose to the receptors selected. Section 3.4, Toxicity Assessment, summarizes the toxicity of the COPCs including both potential carcinogens and noncarcinogens. Section 3.5, Risk Characterization, includes a summary of Site risks and an uncertainty analysis. Table 3-1 (Selection of Exposure Pathways) provides a conceptual model for the Site, identifying the exposure media, exposure points, receptors, and routes of exposure quantitatively evaluated as part of the baseline human health risk assessment.

3.1.2 Identification of Current/Future Exposure Points and Receptors

The purpose of this section is to describe current and future exposure points and receptors selected for evaluation in the human health risk assessment, based on land use, Site characteristics and history.

The Southwest Properties consist of three adjacent properties with soil and groundwater contamination, each with unique ownership and land use histories (see Section 1) and contaminant sources (see Section 2). The Aberjona, Whitney and Murphy properties are, therefore, evaluated as separate exposure points in the risk assessment. The existing Aberjona residence is evaluated as a separate exposure point for the vapor intrusion pathway. The wetland located between the upland portions of the Murphy, Whitney, Wildwood and Aberjona properties (Murphy Wetland) is also evaluated as a separate exposure point because it may have been impacted by more than one of these properties or by other neighboring properties. Approximately 54-percent of the wetland lies on the Murphy property. The remainder is located on the Whitney property (approximately 31 percent) and the Wildwood property (approximately 15 percent). In addition, the potential for groundwater use is evaluated in the future timeframe as a separate site-wide residence exposure point that accounts for potential future potable use of contaminated groundwater originating from the Southwest Properties, as well as shallow groundwater exposures to construction workers during excavations at each of the properties.

A summary of the exposure points evaluated in this risk assessment is provided below by scenario.

Exposure Point	Current Scenario	Future Scenario
Aberjona Soil	X	X
Whitney Soil	X	X
Murphy Soil	X	X
Murphy Wetland Sediment/Surface Water	X	X
Existing Aberjona Residence Indoor Air	X	X
Site Groundwater*	N/A	X

Notes: N/A – Not applicable X – Included exposure point

*Site Groundwater exposures include site-wide residential tap water usage and property-specific construction worker contact while excavating.

Figures 3-1A and 3-1B depict the current and future exposure points, respectively.

Current Receptors. The Southwest Properties are commercially active and zoned industrial (City of Woburn, 2012). Surrounding properties are also industrially zoned. Consequently, current human exposures evaluated in this risk assessment are primarily associated with commercial use, though there is an existing occupied residence on the Aberjona property. Each property has two or more buildings that may be occupied by commercial workers, recreational users (the ice skating rink at the Aberjona property only) or residents (the existing Aberjona residence).

Contaminants present in soil and groundwater could impact indoor air in occupied buildings through gas phase migration. The indoor air pathway is typically evaluated where contaminants in soil or groundwater with the potential to impact indoor air (i.e., sufficient volatility and toxicity) are located in close proximity to an occupied building. Because contaminants with the potential to impact indoor air were detected in soil and groundwater near the current on-property buildings, subslab soil gas sampling was conducted in 2010 beneath each of the commercial on-property buildings, except for the ice skating rink located on the Aberjona property which was constructed with a vapor barrier to mitigate a potential vapor intrusion pathway. Subslab soil gas and indoor air sampling was conducted in 2013 at the existing Aberjona residence. Of the three commercial properties, only the commercial building on the Aberjona property is considered "occupied" (i.e., workers present consistently for 8-hour shifts). The Whitney building is

primarily used for storage with workers present in the building only briefly at the beginning or end of each work day to pick up or drop off equipment and supplies or intermittently for longer periods of time (e.g., to periodically service, repair or inventory equipment). The Murphy building is used primarily for equipment storage, with one small office space that is used for records storage and intermittent occupancy. A qualitative vapor intrusion discussion for the on-property buildings is presented in subsection 3.2.3.2. The vapor intrusion pathway at the existing Aberjona residence has been evaluated quantitatively.

There is no potable or non-ingestion use of groundwater at the Site. Site facilities are connected to the municipal water supply. Therefore, groundwater contaminant exposures are limited to potential impacts to indoor air in the occupied buildings, assessed through the collection of subslab soil gas and/or indoor air data, as discussed above.

Current soil exposures are limited to surface soils (0 to 2 feet) because excavation or invasive construction activities are not occurring at this time. Consequently, there are no current exposures to deeper soils (up to 15 feet in depth) because there are no activities occurring that would bring contaminated soil at depth to the ground surface.

Most areas of known soil contamination are currently fenced or paved, which limits access by trespassers and other non-commercial receptors. However, trespassers may gain access to unsecure areas and incur exposure to contaminated surface soil. The 2006 risk assessment evaluated current trespasser exposures to surface soil within the "Aberjona Triangle", the current location of the newly-constructed ice skating rink. This area is now largely covered by the skating rink building or pavement, preventing current exposures to soil. The front gate of the Whitney property is unsecured. Consequently, trespassers are assumed to freely access the Whitney property and incur exposure to contaminated surface soil. The remainder of the Aberjona property (i.e., the former automotive salvage yard) and the Murphy property are not accessible to trespassers due to the presence of a fence, locked gates, and/or a concrete wall.

The western boundary of the Whitney property abutting the Murphy Wetland is not fenced and the wetland is accessible from the unsecure Whitney property; therefore, the Murphy Wetland is

currently accessible to a trespasser. A portion of the wetland is only seasonally ponded; therefore, exposure to sediments in the entire wetland is evaluated. As with soil, sediment exposure in the Murphy Wetland is limited to the surficial interval since intrusive/excavation activities are not occurring in the wetland. Wading rather than swimming is the primary type of activity assumed for the Murphy Wetland due to the shallow depth of surface water. Commercial workers are assumed to not enter the wetland as part of job-related activities. The evaluation of trespasser exposures provides a conservative indication of commercial exposures should they be occurring.

Future Receptors. Commercial land use is assumed to continue in the future, except for continued use of the existing Aberjona residence for residential use and the ice skating rink for recreational use. Since fencing, gates, and pavement may be removed in the future, trespassers or other non-commercial receptors may access the properties and incur exposures to site-related contaminants with increased frequency compared to current receptors. Future commercial workers and trespassers are assumed to be exposed to surficial soil contaminants, assuming pavement is removed or falls into disrepair in the future allowing exposure to soils that are currently located beneath pavement.

Future development or improvements at the Southwest Properties may require excavation or construction activities. Therefore, construction-related exposures to surface soil (0 to 2 feet) and subsurface soil (2 to 15 feet) are possible. Future exposures may also include impacted outdoor air in construction settings (e.g., trenches) and direct contact exposures to shallow groundwater at each of the properties. Soil and groundwater sampling locations as deep as 15 feet are evaluated for the outdoor trench air and direct contact exposure pathways.

A potential redevelopment option includes expanded use of the properties for recreational activities with the construction of additional on-site recreational facilities. Because the change in land use may result in the movement of soils currently at depth to the surface, future recreational soil exposures are assumed for both the surface and subsurface interval. In addition, future recreational exposures to surface water and sediment are evaluated. Recreational users are likely to visit the site with greater frequency than trespassers.

Due to the predominant commercial nature of the surrounding area and the mapped 100-year floodplain over portions of each of the properties, future residential development of the Aberjona, Whitney and Murphy properties is considered highly unlikely and has not been quantitatively evaluated, though the existing residence at the Aberjona property will likely remain residential in the future. Evaluation of the young child recreational user will provide an indication of the potential risk to the sensitive young child resident receptor population.

Commercial or recreational buildings could be constructed in any area of the Southwest Properties, except the Murphy Wetland. Therefore, indoor air impacts attributable to contaminants in soil and groundwater via a complete vapor intrusion pathway are possible in the future. This exposure pathway is further discussed in subsection 3.2.3.2.

MassDEP prepared a Groundwater Use and Value Determination (MassDEP, 2004; EPA, 2004a and 2005a) for the Wells G&H Superfund Site in accordance with 1998 Memorandum of Agreement between EPA and MassDEP (Figure 3-2). MassDEP concluded a "medium" groundwater use and value determination was appropriate for the Wells G&H aquifer because of its significant current and future ecological value to the Aberjona River and associated wetlands and its potential human value as a drinking water supply in the future. Based upon this determination, future potable use of Site groundwater by a resident is possible, and is evaluated as a tap water exposure point. All groundwater from the Site, regardless of depth, is evaluated in this scenario due to the mobile nature of ground water (horizontal gradients and flow directions are well established) and the potential for groundwater to be pumped, rendering exposure to groundwater from any area of the Site possible. Construction worker exposure to contaminants in shallow groundwater present at each property is also evaluated, as well as the impacts from groundwater on the vapor intrusion pathway and exposures resulting from groundwater discharge to surface water. Other groundwater uses identified in the determination (e.g., industrial process use) will require further evaluation before groundwater is used for these purposes in the future. A copy of the MassDEP's Groundwater Use and Value Determination can be found in Appendix E.3.

3.2 Hazard Identification

The purpose of this section is the determination of the type and amount of chemicals present at the Site and the selection of the COPCs with regard to human health. In addition, this section summarizes the methodology used to determine EPCs for COPCs in each medium.

Environmental data used in this hazard identification are from samples that were collected during several sampling events conducted by property operators, Settling Defendant, and split samples collected by EPA. Soil, sediment and surface water data collected prior to 2003 and used in this risk assessment are contained in the following three main data source documents:

- RETEC 1994, *Draft Remedial Investigation, Southwest Properties, Wells G&H Site, Woburn, Massachusetts, 1994*.

- RETEC 2003, *Supplemental Remedial Investigation, Southwest Properties, Volumes I through XXIII, Wells G&H Site, Woburn, Massachusetts.* Prepared by the RETEC Group, Inc., Concord, Massachusetts, August 2003.

- TRC 2004, *"EPA/TRC and RETEC Split Sample Comparison Report for the Wells G&H – Southwest Properties, Supplemental Remedial Investigation, Woburn, Massachusetts.* Prepared by TRC Environmental Corporation, Lowell, Massachusetts, February 2004.

Additional data for the Murphy property were obtained from:

- Clean Harbors 1998, *Corrective Action Investigation Report (Part II)*, Volume I of I, Murphy's Waste Oil Services, Inc., Woburn, Massachusetts, *1998*.

- Clean Harbors 1996, *Corrective Action Investigation Report*, Volumes 1, 2, and 3. Murphy's Waste Oil Service, Inc., 252 Salem Street, Woburn, Massachusetts, April 15, 1996.

In addition to these historical data for soil, sediment and surface water, additional data collected at the request of EPA during the 2010/2011/2013 supplemental sampling events for soil, groundwater, subslab soil gas and indoor air (see discussion in Section 2) were used in this hazard identification. Only the most recent (2011 and 2013) groundwater data were quantitatively used as these data are most representative of current Site conditions.

Data available from prior documents/investigation efforts at the Site, and certain data contained in the above-referenced documents, were deemed unsuitable for use in the human health risk assessment. The reasons for this determination are summarized below:

- **Historical (pre-2011) Groundwater Data.** Historical groundwater samples collected to characterize groundwater quality for the Aberjona, Whitney and Murphy properties have not been quantitatively evaluated as these data are unlikely to be representative of current groundwater conditions. Instead, representative groundwater sampling data collected in 2011 and 2013 from across the three properties using low-flow sampling procedures have been quantitatively evaluated. For monitoring wells that were sampled in both 2011 and 2013, the maximum result for each analyte over the two sampling rounds was quantitively evaluated.

- **Hexavalent Chromium Data.** Hexavalent chromium soil samples collected prior to the 2002 (RETEC, 2003; TRC, 2004) investigations were analyzed using a colorimetric method or the analytical method was undocumented. Historical groundwater data for hexavalent chromium were analyzed using Ultraviolet/Visible Spectroscopy (Method 7196A). Method comparison data collected for the Wells G&H OU-3 risk assessment indicate that ion chromatography (Method 7199) is the preferred method for hexavalent chromium in solid matrices. Therefore, hexavalent chromium soil data presented in Clean Harbors 1998 and 1996 were not quantitatively used in this risk assessment. Only hexavalent chromium data obtained using the ion chromatography method for soil and the Ultraviolet/Visible Spectroscopy Method (Method 7196A) for groundwater were quantitatively evaluated in the human health risk assessment.

- **Total Petroleum Hydrocarbons Data.** Total Petroleum Hydrocarbon data from the Murphy property documented in Clean Harbors 1996 and 1998 were converted to EPH petroleum hydrocarbon ranges based MassDEP guidance for the assessment of risk from petroleum contamination (MassDEP, 2002). Since TPH is essentially a summation of the 3 EPH hydrocarbon fractions (i.e., C9-C18 aliphatics, C19-C36 aliphatics, and C11-C22 aromatics), it is possible to "convert" TPH data into the EPH fractions, by making informed and reasonably conservative judgments on the chemistry of the TPH data.

  In using and applying assumptions on the composition of petroleum hydrocarbons, relevant factors considered, include (1) level of certainty of identification of petroleum product(s) released at the site, (2) the age of the releases and how the releases may have weathered over time, (3) the availability of co-located EPH data to use for correlations (4) reliability, validity, and bias of TPH/screening techniques, and (5) sensitivity of pollutant receptors. Given the wide variability in "TPH" analytical methods and inherent biases of these methods, the variety of the petroleum products that may have been released at the properties, the differential weathering of the released material that may have occurred, and the lack of co-located EPH data, the determination of true TPH concentration was approached conservatively. Since no finger print data was available and given the nature of historic site operations, TPH was considered to be 100% C11-C22 aromatics, the most toxic EPH fraction.

- **Broad Soil Composite Depth Intervals.** Prior soil data from the Whitney property collected by GHR Engineering Associates in 1988 and a limited number of soil samples collected from the Murphy property by Clean Harbors (Clean Harbors, 1998) were collected as composites from broad depth intervals (e.g., 0 to 8 feet). Samples from such broad composite intervals are unsuitable for use in the human health risk assessment because the exposure interval (surface or subsurface) cannot be determined.

3.2.1 Background and Reference Samples

Background samples for soil and groundwater were collected as part of investigation activities conducted at the Site. Background locations for surface soil are identified as samples AB-10SS and AB-17SS (Aberjona property), WB-5SS and WB-14SS (Whitney property), and MR-8SS and MR-19SS (Murphy property). Subsurface soil background samples were collected in the same locations as the background surface soils and include AB-10D, AB-17D, WB-5D, WB-14D, MR-8D and MR-19D. Groundwater data representative of background for the Site were collected from Murphy property wells MW-1 and MW-2 prior to 2011.

For sediment and surface water, the reference data set used by EPA as part of the Wells G&H OU-3 risk assessment (EPA, 2004a and 2005a) is the most appropriate source of data to assess background conditions for the Murphy Wetland.

Reference/background samples were collected from areas not considered to be affected by Wells G&H OU-3 or OU-2 site activities and not displaying visual evidence of contamination. The Southwest Properties background sampling locations are shown in Figure 2-1 and sample-specific analytical results are presented in the media-specific tables in Appendix B.1 of this report. Wells G&H OU-3 wetland reference locations are identified as stations 24, HB and SA. Summarized analytical data for these reference locations are presented in Appendix B.2. Reference or background analyte concentrations do not impact the selection of COPCs (subsection 3.2.3) or the calculation of EPCs (subsection 3.2.4).

3.2.2 Data Used in Risk Assessment

As discussed in Section 2, environmental data considered for use in this risk assessment were collected during several sampling events. Detailed discussions of sampling approaches and the quality assurance and control activities implemented during the collection of the data, where available, are provided in the source documents and in Section 2 for the 2010/2011/2013 supplemental sampling. A discussion of data validation procedures is also provided in Section 2.

The following procedures used to summarize the analytical data are in accordance with *Risk Assessment Guidance for Superfund (RAGS)* (EPA, 1989) and supplemental guidance (EPA, 1992). The analytical data were summarized by environmental medium and grouped into exposure areas. Outdoor air data, applicable to worker exposures in an excavation trench, were modeled from property-specific soil and shallow groundwater data using dilution/dispersion modeling (see Appendix B.3). The transport and dilution/dispersion model used property-specific information on the depth to groundwater (i.e., observed minimum depth to groundwater from the available record) as well as appropriate values for soil properties to establish reasonably conservative site-specific modeled exposure point concentrations for air in an excavation trench.

For the baseline risk assessment, the following media and exposure points were selected for evaluation (either quantitative or qualitative):

- Surface soil, subsurface soil, shallow groundwater, and subslab soil gas at the Aberjona property;
- Surface soil, subsurface soil, shallow groundwater, and subslab soil gas at the Whitney property;
- Surface soil, subsurface soil, shallow groundwater, and subslab soil gas at the Murphy property;
- Subslab soil gas and indoor air at the existing Aberjona residence to assess the vapor intrusion indoor air pathway;
- Site-wide groundwater for the future residential tap water scenario; and
- Surface water and sediment in the Murphy Wetland.

The following sections summarize the environmental data available for use in the risk assessment for each of the exposure points.

3.2.2.1 Aberjona Property Data

Surface soil, subsurface soil, groundwater, subslab soil gas and indoor air samples were collected from the Aberjona property. Analytical results of compounds detected in these media are presented in Appendix A. Sampling locations for sampling conducted at the Aberjona property and used in this risk assessment can be found on Figure 2-1.

For the purposes of this risk assessment, only groundwater results from the 2011 and 2013 sampling events have been used quantitatively. The last documented prior groundwater monitoring event at the Aberjona property took place in 2002. Groundwater analytical data available for the Aberjona property from 2002 (or prior) are unlikely to represent current conditions and, therefore, have not been quantitatively used in the risk assessment.

Surface soil samples are defined as the most surficial interval of overburden material. Soil from the 0 to 2 foot depth interval is included as surface soil since these represent contaminant concentrations that humans may currently encounter. Samples bolded in the following table were collected from beneath pavement or existing buildings and therefore, have not been used to assess current surface soil exposures. However, the bolded samples were used to assess future surface soil exposures. Surface soil samples collected from the Aberjona property are summarized below:

Aberjona Property Surface Soil Samples (0 to 2 feet)		
Sample Name	**Sample Depth (feet)**	**Source Reference/Notes**
AB-SS1	**0-0.5**	**RETEC 1994, 1993 Sampling Event**

AB-214	**0-2**	**AECOM, 2010 Sampling Event**

Bolded locations are currently covered with pavement or buildings

Subsurface soil samples were also collected from the Aberjona property. Subsurface soil samples are representative of the deeper interval, which human receptors may encounter under future site reuse conditions. The subsurface interval includes soils from 2 to 15 feet below ground surface. Subsurface soil samples collected at the Aberjona property include the following:

Aberjona Property Subsurface Soil Samples (2 to 15 feet)		
Sample Name	**Sample Depth (feet)**	**Source Reference, Notes**
AB-SS1D	4-5	RETEC 1994, 1993 Sampling Event

Groundwater samples were collected from a variety of depth intervals at the Aberjona property, including bedrock. Groundwater monitoring well screens were installed at depths that ranged from 3 to 148 feet below ground surface. Groundwater samples collected at the Aberjona property, and utilized in this human health risk assessment, include the following:

Aberjona Property Groundwater Monitoring Locations		
Sample Name	**Screen Interval (feet)**	**Source Reference, Notes**
AB-1	6.5-11.5	AECOM, 2013 Sampling Event
AB-1M	50-60	AECOM, 2013 Sampling Event

S-77S	25-30	AECOM, 2013 Sampling Event

Shallow groundwater monitoring well data were evaluated separately for the property-specific construction worker scenario and include data from monitoring wells AB-1, AB-201, AB-203, AB-206, AB-211, AB-214, AB-2SS, AB-4SS, S-77S, S-83SS and BSSW-16. Four subslab soil gas samples were collected from beneath the Aberjona property commercial building (AVP-203, AVP-204, AVP-205 and AVP-206). One subslab soil gas sampling location, one basement indoor air sampling location, one first floor indoor air sampling location and one upwind outdoor ambient air sampling location were identified and sampled at the existing Aberjona residence in April and August 2013. Sampling locations are shown on Figure 2-1. A comprehensive tabulation of these data may be found in Appendix A.1 (Soil Data Summary Table), A.2 (Groundwater Data Summary Tables), A.5 (Subslab Soil Gas Data Summary Table) and A.6 (Existing Aberjona Residence Indoor Air and Subslab Soil Gas Data Summary Table).

Summaries of current surface (accessible locations), future surface (accessible and currently inaccessible locations) and subsurface soil data are presented in Tables 3-2.1.1, 3-2.1.2 and 3-2.1.3, respectively, for the Aberjona property. Shallow groundwater data for the Aberjona property are summarized in Table 3-2.2.2. All groundwater data for the three properties are

combined and discussed in Section 3.2.2.4. The subslab soil gas data for the Aberjona property are summarized in Table 3-2.6. The indoor air data for the existing Aberjona residence are summarized in Appendix D, Table 2. Each of the summary tables for chemicals detected in soil, groundwater, subslab soil gas and indoor air provide the frequency of detection, range of SQLs for samples where compounds were not detected, range of detected concentrations, and locations of maximum detected results.

3.2.2.2 Whitney Property Data

Surface soil, subsurface soil, groundwater and subslab soil gas samples were collected from the Whitney property. One sediment sample was collected from the Whitney property, which is discussed later as part of the Murphy Wetland (Section 3.2.2.6). Analytical results of compounds detected in these media are presented in the Appendix A. Sampling locations for sampling conducted at the Whitney property and used in this risk assessment can be found on Figure 2-1.

For the purposes of this risk assessment, only groundwater results from the 2011 and 2013 sampling events have been used quantitatively. The last documented prior groundwater monitoring event at the Whitney property took place in 2002. Groundwater analytical data available for the Whitney property from 2002 (or prior) are unlikely to represent current conditions and, therefore, have not been quantitatively used in the risk assessment.

Surface soil samples are defined as the most surficial interval of overburden material. Soil from the 0 to 2 foot depth interval is included as surface soil since these represent contaminant concentrations that humans may currently encounter. Samples bolded in the following table were collected from beneath pavement or existing buildings and therefore, have not been used to assess current surface soil exposures. However, the bolded samples were used to assess future surface soil exposures. Surface soil samples collected from the Whitney property are summarized below:

Groundwater samples were collected from a variety of depth intervals at the Whitney property, including bedrock. Groundwater monitoring well screens were installed at depths that ranged from 3 to 120 feet below ground surface. Groundwater samples collected at the Whitney property and utilized in this human health risk assessment include the following:

Whitney Property Groundwater Monitoring Locations

Shallow groundwater monitoring well data were evaluated separately for the property-specific construction worker scenario and include data from monitoring wells MW-4S, MW-5S, MW-6S, WB-201S, WB-206, WB-209, WB-213, WB-215, WB-216, WB-220 and BSW-2. Five subslab soil gas samples were collected from beneath the Whitney property building (WVP-205, WVP-206, WVP-207, WVP-209 and WVP-211). Sampling locations are shown on Figure 2-1. A comprehensive tabulation of these data may be found in Appendix A.1 (Soil Data Summary Table), A.2 (Groundwater Data Summary Tables), and A.5 (Subslab Soil Gas Data Summary Table).

Summaries of current surface (accessible locations), future surface (accessible and currently inaccessible locations) and subsurface soil data are presented in Tables 3-2.1.1, 3-2.1.2 and 3-2.1.3, respectively, for the Whitney property. Shallow groundwater data for the Whitney property are summarized in Table 3-2.2.2. All groundwater data for the three properties are combined and discussed in Section 3.2.2.4. The subslab soil gas data for the Whitney property are summarized in Table 3-2.6. Each of the summary tables for chemicals detected in soil, groundwater and soil gas provide the frequency of detection, range of SQLs for samples where compounds were not detected, range of detected concentrations, and locations of maximum detected results.

3.2.2.3 Murphy Property Data

Surface soil, subsurface soil, groundwater and subslab soil gas samples were collected from the Murphy property. Samples of surface water and sediment were also collected from the wetland on the Murphy property, but are discussed separately in Section 3.2.2.6. Analytical results of

compounds detected in these media are presented in the Appendix A. Sampling locations for all sampling conducted at the Murphy property and used in this risk assessment can be found on Figure 2-1.

For the purposes of this risk assessment, only groundwater results from the 2011 and 2013 sampling events have been used quantitatively. The last documented prior groundwater monitoring event at the Murphy property took place in 2002. Groundwater analytical data available for the Murphy property from 2002 (or prior) are unlikely to represent current conditions and, therefore, have not been quantitatively used in the risk assessment.

Surface soil samples are defined as the most surficial interval of overburden material. Soil from the 0 to 2 foot depth interval is included as surface soil since these represent contaminant concentrations that humans may currently encounter. Samples bolded in the following table were collected from beneath pavement or existing buildings and therefore, have not been used to assess current surface soil exposures. However, the bolded samples were used to assess future surface soil exposures. Surface soil samples collected from the Murphy property are summarized below:

MW-204	5-15	AECOM, 2011 Sampling Event
MW-206	5-15	AECOM, 2011 Sampling Event

TD – Total Depth (no information on screened interval available)

Shallow groundwater monitoring well data were evaluated separately for the property-specific construction worker scenario and include data from monitoring wells MW-3S, MW-7, MW-9,

MW-12, MW-16, MW-18S, MW-24, MW-201, MW-204 and MW-206. One subslab soil gas sample was collected from beneath the Murphy property building (MVP-206). Sampling locations are shown on Figure 2-1. A comprehensive tabulation of these data may be found in Appendix A.1 (Soil Data Summary Table), A.2 (Groundwater Data Summary Tables), and A.5 (Subslab Soil Gas Data Summary Table).

Summaries of current surface (accessible locations), future surface (accessible and currently inaccessible locations) and subsurface soil data are presented in Tables 3-2.1.1, 3-2.1.2 and 3-2.1.3, respectively, for the Murphy property. Shallow groundwater data for the Murphy property are summarized in Table 3-2.2.2. All groundwater data for the three properties are combined and discussed in Section 3.2.2.4. The subslab soil gas data for the Murphy property are summarized in Table 3-2.6. Each of the summary tables for chemicals detected in soil, groundwater and soil gas provide the frequency of detection, range of SQLs for samples where compounds were not detected, range of detected concentrations, and locations of maximum detected results.

3.2.2.4 Site-Wide Future Residential Tap Water

All groundwater data for the three properties, regardless of depth, were combined to evaluate a site-wide future residential groundwater use scenario. The samples utilized have been previously presented in Sections 3.2.2.1, 3.2.2.2 and 3.2.2.3 for the Aberjona, Whitney and Murphy properties, respectively. All groundwater data combined are summarized in Table 3-2.2.1. The summary table for chemicals detected in groundwater provides the frequency of detection, range of SQLs for samples where compounds were not detected, range of detected concentrations, and locations of maximum detected result.

3.2.2.5 Outdoor Trench Air Data

Volatile contaminants detected in surface soil, subsurface soil and shallow groundwater from the Aberjona, Whitney and Murphy properties were used to estimate outdoor trench air concentrations a worker may be exposed to during trenching activities. Volatile contaminants were defined as those compounds with Henry's Law Constants greater than 1E-05 atm-m^3/mole

and molecular weights less than 200 grams/mole (EPA, 1991a). Consistent with EPA's Draft Subsurface Vapor Intrusion Guidance, the compounds evaluated possessed sufficient volatility and toxicity (EPA, 2002a) to warrant evaluation, plus included compounds that satisfied the molecular weight criterion (EPA, 1991a). Appendix B.3 documents the assumptions used in the modeling of outdoor air trench concentrations as well as inputs to the model. Table 3-2.5 list the soil and groundwater volatile contaminants detected at each exposure point along with their modeled outdoor air trench concentrations assuming summed impacts from both soil and groundwater. Maximum soil and groundwater volatile concentrations were used as inputs to the model. Maximum (i.e., worst-case) air concentrations were derived by summing the contributions from soil and groundwater at each exposure point and are summarized in Appendix B.3. Because only one set of air concentrations were modeled, only one set of concentrations (i.e., maximum modeled concentrations) appear on Table 3-2.5.

3.2.2.6 Murphy Wetland

Sediment and surface water samples were collected from the Murphy Wetland located between the upland portions of the Murphy, Whitney, Wildwood and Aberjona properties. Analytical results of compounds detected in surface water and sediment are presented in Appendix A. Sampling locations for all sampling conducted at the Murphy Wetland and used in this risk assessment can be found on Figure 2-1. For the purposes of the human health risk assessment, substrate collected from within the boundaries of the wetland, whether located beneath standing water or in dry areas, has been classified as sediment.

For the purposes of this risk assessment, only surface water results from the 2002 sampling event are used quantitatively for the Murphy Wetland. Surface water samples collected prior to 2002 are not considered representative of current conditions due to the mobile nature of surface water.

Humans are likely to encounter only surficial sediment in the wetland. The sediment samples collected by RETEC in 2002 and split with EPA were from the 0 to 0.5 foot depth interval. The sediment samples collected by Clean Harbors in 1995 and 1997 were collected from the 0 to 2 foot depth interval. Both sets of samples are considered to represent the surficial interval. Three

samples collected from 0 to 3 feet by RETEC in 1993 have also been used in this evaluation since most of the 0 to 3 foot sampling interval overlaps the 0 to 2 foot interval.

Human exposures are likely to occur only to sediments located below two feet or less of standing water. The depth of surface water at the 2002 sediment sampling locations was approximately 2 feet or less. The depth of surface water, where present at a wetland sample location, is not known for the samples collected by Clean Harbors and RETEC prior to the 2002 RETEC/EPA-split sampling event. However, the standing water tends to disappear in the summer months and during dry periods, when human exposures are most likely to occur. Consequently, all sediments are considered accessible. Sediment samples collected from the Murphy Wetland include:

The surface water samples collected by RETEC in 2002 include the following:

Murphy Wetland Surface Water Samples		
Sample Name	**Sample Depth (feet)**	**Source Reference/Notes**
MW-12SW	≤ 2	RETEC 2003, 2002 Sampling Event
MW-13SW	≤ 2	RETEC 2003, 2002 Sampling Event
BW-4SW	≤ 2	RETEC 2003, 2002 Sampling Event

A comprehensive tabulation of these data may be found in Appendix A.3 (Surface Water Data Summary Table) and A.4 (Sediment Data Summary Table).

Surface water and sediment data for the Murphy Wetland are summarized in Tables 3-2.3 and 3-2.4, respectively. These summary tables for chemicals detected in surface water and sediment provide the frequency of detection, range of SQLs for samples where compounds were not detected, range of detected concentrations, and the locations of maximum detected results.

3.2.2.7 Data Evaluation

The following describes data evaluation and data summary conventions utilized during preparation of the human health risk assessment applicable to qualified data, multi-procedure analytical results, and hexavalent chromium data.

Data were qualified by the analytical laboratory and validated as described in Section 2 of this report. The qualification and validation of the analytical data included a comparison of the site data to corresponding blank (laboratory, field, equipment, and trip) concentration data. Data rejected by the validation ("R" qualified) were not used. Estimated values (e.g., "J" qualified) were used in the risk assessment without modification. One half the SQL value was used for constituents that were reported as not detected above the quantitation limit (e.g., "U" qualified) in the calculation of arithmetic means values. Analytical data from duplicate samples were combined as described in Section 2. Frequency of detection was calculated as the number of samples in which the chemical was detected over the total number of samples analyzed for that chemical after the exclusion of rejected ("R" qualified) data. A duplicate sample was not counted as an additional sample.

Where constituents were detected multiple times in one sample because the constituent is common to multiple analytical procedures (e.g., naphthalene is found on VOC, VPH, SVOC and EPH analyte lists), the maximum detected value was selected for quantitative use. Where the constituent was not detected by any of the procedures, the lowest laboratory reporting limit was utilized.

The 2002 investigation of the Southwest Properties by RETEC included the sampling of soil, sediment and groundwater for hexavalent chromium using ion chromatography (Method 7199) for soil and sediment, and Ultraviolet/Visible Spectroscopy (Method 7196A) for groundwater. The groundwater monitoring conducted on behalf of Clean Harbors at the Murphy property in 2001 also included the analysis of hexavalent chromium by Method 7196A. These analyses were performed for a subset of samples from each medium, with groundwater having the greatest frequency of analysis. For all media, analyses for total chromium were performed at a greater frequency compared to hexavalent chromium; therefore, total chromium provides the greatest spatial coverage.

The results of hexavalent chromium analysis in soil and sediment suggest that hexavalent chromium does not exist at appreciable levels in these media. The maximum detected hexavalent chromium concentration quantified in sediment was 80.8 mg/kg at location MR-18, which had a total chromium concentration of 14,000 mg/kg. Sediment locations with total chromium concentrations less than 340 mg/kg were non-detect for hexavalent chromium. For soil, the maximum detected concentration of hexavalent chromium quantified was 2.6 mg/kg at WB-10 where the total chromium concentration was 31 mg/kg. Soil sampling locations with total chromium concentrations less than 12.5 mg/kg were non-detect for hexavalent chromium. Since hexavalent chromium analyses were not performed at all sampling location, hexavalent chromium concentrations were estimated at locations with only total chromium results. This approach assumed that a percentage of the total chromium is hexavalent chromium, if total chromium levels exceed a threshold concentration. The threshold concentration is the medium-specific level of total chromium where hexavalent chromium was not detected.

In soil and sediment, the hexavalent chromium results were compared to the total chromium results in samples where both analyses were performed to estimate the percentage of hexavalent chromium in the medium. The results of this analysis are summarized below:

In the sediments of the Murphy Wetland, the percentage of hexavalent chromium/total chromium ranged from 0.39 % to 1.07 %. Hexavalent chromium concentrations were estimated for

locations with only total chromium results using the average percentage of hexavalent/total chromium (approximately 0.55%). Sediments with total chromium concentrations less than or equal to 340 mg/kg (the threshold concentration for sediment) are assumed to be non-detect for hexavalent chromium.

In soil, the Whitney property had the greatest number of hexavalent chromium analyses (seven samples). In contrast, the Aberjona property had one hexavalent chromium analysis in soil and the Murphy property had two. Hexavalent chromium was not detected in the soil samples collected at the Aberjona and Murphy properties, but it was detected in three of the seven samples collected at the Whitney property. Based on the Whitney property detect soil data, the percentage of hexavalent chromium/total chromium ranged from 0.35 % to 8.39 %. Hexavalent chromium concentrations were estimated for locations with only total chromium results using the average percentage of hexavalent/total chromium (approximately 3%). Soil with total chromium concentrations less than or equal to 12.5 mg/kg (the threshold concentration for soil) are assumed to be non-detect for hexavalent chromium. The total chromium concentrations at the Whitney property (maximum of 375 mg/kg) are similar to those at the two other properties (544 mg/kg at the Aberjona property and 400 mg/kg at the Murphy property), therefore the hexavalent chromium percentage and threshold concentration derived for the Whitney property were applied to these properties.

Hexavalent chromium was not detected in groundwater based on the analysis of 45 samples in 2001 and 2002. Therefore, total chromium concentrations in 2011 groundwater samples were qualitatively evaluated as trivalent chromium for the estimation of risk. Since hexavalent chromium analysis was not performed for surface water, total chromium detected in this medium was conservatively assumed to exist entirely as hexavalent chromium.

Since certain soil and sediment samples were collected as splits during the RETEC 2002 sampling event, more than one set of analytical results were available for some sampling locations. For these sampling locations, the multiple results were treated as unique samples rather than as duplicate samples (i.e., the multiple results were not averaged as described in Section 2 for duplicates). This is consistent with the approach used in the Wells G&H OU-3 risk

assessment, where sediment samples collected during multiple rounds of sampling from the same sampling location were treated as separate samples. The approach was adopted for split-samples collected for this baseline risk assessment and applied to soil and sediment. Therefore, in determining the frequency of detection for split samples, the analytical results from the split samples were considered as separate values.

3.2.3 Identification of COPCs

The scope of the baseline human health risk assessment includes identification of COPCs based on the chemical substances found at the Site. The list of COPCs was developed using the screening process described below. For surface soil, subsurface soil, groundwater, sediment, surface water, subslab soil gas, indoor air and modeled trench air, available and appropriate data for the human health exposure points were combined for each medium to select COPCs. Combining all data for a given medium results in a conservative list of COPCs for that medium.

3.2.3.1 Selection Criteria

The maximum detected concentration of a chemical in surface soil, subsurface soil, groundwater, sediment, surface water, subslab soil gas, indoor air and modeled outdoor trench air was compared to Regional Screening Levels (RSLs) published by EPA (EPA, 2013). RSLs are risk-based concentrations that are intended to assist risk assessors and others in initial screening-level evaluations of environmental contaminant concentrations. RSLs are chemical concentrations back-calculated using toxicity criteria and either a $1x10^{-6}$ target risk level for potential carcinogens or a hazard quotient (HQ) of 1 for noncarcinogens. For purposes of this screening analysis, a HQ of 0.1 was used to add a ten-fold measure of safety to reduce the chance of omitting chemicals from the list of COPCs that could contribute to a total hazard index (HI) of 1. To accomplish this, RSLs for noncarcinogenic chemicals were divided by 10 prior to comparison to maximum detected values. Tap water RSLs were used for comparison to maximum detected surface water and groundwater concentrations. The comparison of surface water concentrations to tap water RSLs provides a conservative screening evaluation. Ambient Water Quality Criteria (AWQCs; EPA, 2009b) and Maximum Contaminant Levels (MCLs; EPA, 2012) were also used

to screen for COPCs in surface water and groundwater, respectively. Residential soil RSLs were used for comparison to maximum detected surface soil and subsurface soil concentrations, as well as maximum detected sediment concentrations. Industrial air RSLs were used as screening criteria for maximum modeled outdoor air concentrations, applicable to worker exposures in an excavation trench. The industrial air RSLs were multiplied by 10 to generate soil gas screening levels (EPA, 2002a), applicable to the existing commercial buildings at each of the properties. Residential air RSLs were used as screening criteria for maximum indoor air concentrations detected at the existing Aberjona residence.

RSLs are not published for petroleum hydrocarbon fraction data obtained from VPH/APH (C5-C8 aliphatics, C9-C12 aliphatics, and C9-C10 aromatics) and EPH (C9-C18 aliphatics, C19-C36 aliphatics, and C11-C22 aromatics) analyses. In lieu of RSLs or other suitable criteria from EPA, the maximum detected hydrocarbon fraction concentrations in each medium were compared to values derived using EPA's on-line RSL calculator, default scenario-specific exposure assumptions and EPA's toxicity values for the hydrocarbon fractions (EPA, 2009c). RSLs calculated for the hydrocarbon fractions were adjusted for noncarcinogens as previously described.

A maximum detected chemical concentration less than its screening value indicated that the excess lifetime cancer risk associated with exposure to that chemical concentration would be less than one in one million and the HQ associated with exposure would be less than 0.1. Chemicals detected at concentrations below their screening criteria were, therefore, eliminated from further evaluation. All chemicals with maximum concentrations greater than the relevant screening criteria were selected as COPCs. Comparisons of maximum concentrations to screening criteria are presented in the data summary tables for each medium, as summarized below:

COPC Selection Tables				
Table No.	**Medium**	**Exposure Medium**	**Time Frame**	**Note**
3-2.1	Soil	Soil	Current/Future	
3-2.2	Groundwater	Groundwater	Future	
3-2.3	Surface Water	Surface Water	Current/Future	
3-2.4	Sediment	Sediment	Current/Future	
3-2.5	Soil/Groundwater	Outdoor Trench Air	Future	

COPC Selection Tables				
Table No.	**Medium**	**Exposure Medium**	**Time Frame**	**Note**
3-2.6	Soil Gas	Indoor Air	Current/Future	See Section 3.2.3.2
Appendix D; Table 2	Indoor Air	Indoor Air	Current/Future	Existing Aberjona Residence

For certain analytes that lack compound-specific screening criteria (e.g., endrin aldehyde), a surrogate compound was selected (e.g., endrin) and its screening criteria was used for COPC screening. Specific instances where surrogate assignments were made are identified in footnotes in the COPC selection tables.

For three analytes (mercury, chromium and cyanide), multiple RSLs are available for use as COPC selection criteria. For mercury in sediment, the RSL for methyl mercury in residential soil was compared to the maximum detected result for mercury. For mercury in soil, groundwater and surface water, the medium-specific RSLs for mercuric chloride were compared to the maximum detected mercury results. For cyanide, RSLs for free cyanide were used in COPC selection for soil, sediment, surface water and groundwater. The RSL used for chromium depended on the availability of hexavalent chromium data. In soil and sediment, both total chromium and hexavalent chromium were detected. In this case, the RSL for chromium VI in residential soil was compared to maximum detected hexavalent chromium result and the RSL for trivalent chromium was compared to the maximum detected total chromium result. In groundwater, analyses were performed for both hexavalent and total chromium. No hexavalent chromium was detected in groundwater. In this case, the RSL for trivalent chromium was compared to the maximum detected result for total chromium in groundwater. In surface water, only total chromium analyses were performed. In this case, the RSL for hexavalent chromium was conservatively compared to the maximum detected total chromium result in surface water.

Four essential human nutrients lacking screening criteria (i.e., calcium, magnesium, potassium and sodium) were not considered COPCs as these nutrients are only toxic at very high concentrations.

Since EPA does not provide a RSL for lead, the maximum detected lead concentration in sediment and surface soil was evaluated relative to the residential soil screening level of 400 mg/kg (EPA, 1994a). The maximum lead concentration in surface water and groundwater was evaluated relative to the Safe Drinking Water Act (SDWA) action level of 0.015 mg/l, a criterion protective of blood lead levels in children (EPA, 2012).

3.2.3.2 Chemicals Selected as COPCs

This subsection describes the chemicals selected as COPCs and refers to lists of the selected chemicals.

COPCs in Soil. Constituents detected in the surface and subsurface soil samples collected from the three Southwest Properties are summarized in Tables 3-2.1. Tables 3-2.1 lists, by property, chemicals detected in surface soil and subsurface soil and identifies the chemicals selected as COPCs based on comparison to residential soil RSLs.

The 25 soil COPCs for the Aberjona property are summarized below:

Aberjona Property Soil COPCs		
naphthalene	C9-C18 aliphatics	cobalt
2-methylnaphthalene	C11-C22 aromatics	iron
benzo(a)anthracene	total PCBs	lead
benzo(b)fluoranthene	PCB TEQ	manganese
benzo(k)fluoranthene	aluminum	nickel
benzo(a)pyrene	antimony	thallium
indeno(1,2,3-cd)pyrene	arsenic	vanadium
dibenz(a,h)anthracene	cadmium	
C9-C10 aromatics	chromium VI	

The 55 soil COPCs for the Whitney property are summarized below:

Whitney Property Soil COPCs		
1,2,3-trichlorobenzene	bis(2-ethylhexyl)phthalate	4,4'-DDE
naphthalene	benzo(b)fluoranthene	4,4'-DDT
vinyl chloride	benzo(k)fluoranthene	total PCBs
1,1-dichloroethane	benzo(a)pyrene	PCB TEQ
cis-1,2-dichloroethene	indeno(1,2,3-cd)pyrene	aluminum
carbon tetrachloride	dibenz(a,h)anthracene	antimony
benzene	C5-C8 aliphatics	arsenic
trichloroethene	C9-C12 aliphatics	cadmium
tetrachloroethene	C9-C10 aromatics	chromium VI
ethylbenzene	C9-C18 aliphatics	cobalt
xylenes (total)	C11-C22 aromatics	copper
1,3-dichlorobenzene	alpha-chlordane	iron
1,4-dichlorobenzene	gamma-chlordane	lead
1,2,4-trichlorobenzene	alpha-BHC	manganese
2-methylnaphthalene	delta-BHC	mercury
1,1-biphenyl	gamma-BHC	thallium
carbazole	heptachlor	vanadium
benzo(a)anthracene	heptachlor epoxide	
chrysene	dieldrin	

The 31 soil COPCs for the Murphy property are summarized below:

Murphy Property Soil COPCs		
1,2,4-trimethylbenzene	dibenz(a,h)anthracene	arsenic
naphthalene	C5-C8 aliphatics	chromium VI
trichloroethene	C9-C12 aliphatics	cobalt
ethylbenzene	C9-C10 aromatics	iron
xylenes (total)	C9-C18 aliphatics	lead
carbazole	C11-C22 aromatics	manganese
benzo(a)anthracene	dieldrin	thallium
benzo(b)fluoranthene	total PCBs	vanadium
benzo(k)fluoranthene	PCB TEQ	
benzo(a)pyrene	aluminum	

Murphy Property Soil COPCs		
indeno(1,2,3-cd)pyrene	antimony	

More COPCs were identified for soil than in the 2006 baseline risk assessment due to changes in RSLs and the more extensive sampling of potential source areas that was conducted in 2010 and 2011. The additional sampling has reduced the uncertainty associated with the risk assessment.

COPCs in Groundwater. Constituents detected in the groundwater samples collected from the Southwest Properties are summarized in Table 3-2.2. This table identifies the chemicals selected as COPCs in groundwater based on comparison to screening criteria. Table 3-2.2 lists chemicals analyzed for in groundwater regardless of depth or formation (i.e., overburden or bedrock) and identifies the COPCs for the groundwater exposure scenarios.

The maximum detected results for 60 contaminants for all groundwater regardless of depth exceed their respective screening criteria and were selected as COPCs.

The 60 COPCs in groundwater regardless of depth are summarized below:

Groundwater COPCs		
benzene	vinyl chloride	delta-BHC
chlorobenzene	xylenes (total)	dieldrin
1,2-dichlorobenzene	C5-C8 aliphatics	endrin
1,3-dichlorobenzene	C9-C12 aliphatics	endrin ketone
1,4-dichlorobenzene	C9-C10 aromatics	lindane
1,1-dichloroethane	C9-C18 aliphatics	gamma-chlordane
1,2-dichloroethane	C11-C22 aromatics	heptachlor
cis-1,2-dichloroethene	benzo(a)anthracene	heptachlor epoxide
trans-1,2-dichloroethene	benzo(a)pyrene	aluminum
1,1-dichloroethene	benzo(b)fluoranthene	antimony
1,4-dioxane	indeno(1,2,3-cd)pyrene	arsenic
ethylbenzene	2-methylnaphthalene	cadmium
methyl tert butyl ether	naphthalene	cobalt

Groundwater COPCs		
methylene chloride	total PCBs	iron
tetrachloroethene	PCB TEQ	lead
toluene	4,4'-DDD	manganese
1,2,3-trichlorobenzene	4,4'-DDT	selenium
1,2,4-trichlorobenzene	aldrin	vanadium
1,1,1-trichloroethane	alpha-BHC	
1,1,2-trichloroethane	alpha-chlordane	
trichloroethene	beta-BHC	

Though the 2011 and 2013 groundwater sampling data have been used preferentially over the 2002 sampling data, a similar, though somewhat more extensive list, of COPCs has been identified than was identified in the 2006 HHRA using the 2002 sampling data. The more analytically comprehensive groundwater data has reduced the uncertainty associated with the baseline risk assessment.

COPCs in Outdoor Trench Air. Volatile contamination in outdoor trench air can be attributed to migration from source media. Contaminants detected in soil and groundwater with Henry's Law constants greater than 1E-05 atm-m^3/mole and molecular weights less than 200 grams/mole (EPA, 1991a) were selected for modeling. The maximum detections of the selected compounds along with the appropriate compound-specific parameters were used as inputs to dilution/dispersion models to estimate the airborne concentration based on property-specific maximum concentrations in the source media. The maximum modeled contributions from soil and groundwater were summed to estimate a maximum airborne concentration that might be expected in outdoor trench air. The summed results for outdoor air were then compared to industrial air RSLs, applicable to worker exposures in an excavation trench. Those compounds that exceeded industrial air RSLs were retained as COPCs.

Appendix B.3 contains tables that summarize compounds detected in soil and shallow groundwater from the three Southwest Properties that meet the Henry's Law and molecular weight criteria described above. These compounds were then modeled using property-specific parameters such as minimum depth to groundwater to estimate reasonably conservative outdoor

trench air concentrations (see Appendix B.3 for the model documentation). The summing of the impacts from soil and groundwater for each property are also presented in Appendix B.3.

Only one outdoor trench air COPCs was selected for quantitative evaluation, as presented in Table 3-2.5. The selected COPC is trichloroethene at the Whitney property. Because no outdoor trench air COPCs were selected for the Aberjona and Murphy properties, no quantitative evaluation of the outdoor trench air pathway has been performed at these two properties.

Potential worker exposures to significant levels of VOCs in outdoor trench air were documented during the 2010 and 2011 test pit excavation activities near the rear of the Whitney building to locate the presumably abandoned drain line. During initial excavation, the field PID instrument recorded elevated VOC concentrations within 15 feet of the exposed sewer pipe ranging from approximately 1,340 ppm to over 9,999 ppm. As a result, the field staff personnel upgraded PPE to include the use of half-faced respirators with organic vapor cartridges (Appendix E.1).

COPCs in Surface Water. Surface water was sampled only for inorganics (metals and cyanide). Previous surface water sampling results were non-detect for organic constituent COPCs detected in site soils; therefore organic analyses of surface water samples were not warranted. Constituents detected in unfiltered Murphy Wetland surface water samples are summarized in Table 3-2.3. Table 3-2.3 lists chemicals detected in surface water from the Murphy Wetland as well as the chemicals selected as COPCs based on comparison to tap water RSLs and AWQCs.

The five surface water COPCs for the Murphy Wetland are summarized below:

Surface Water COPCs – Murphy Wetland		
chromium VI	cyanide	manganese
cobalt	iron	

A similar list of surface water COPCs was identified in the 2006 baseline risk assessment since the same data set was used for this and the 2006 COPC selection process. Slight differences in the lists of COPCs are due to changes in RSL that have occurred since 2006.

COPCs in Sediment. Constituents detected in the sediment samples collected from the Murphy Wetland and quantitatively evaluated in the human health risk assessment are summarized in Table 3-2.4. Table 3-2.4 lists chemicals detected in sediment samples from the Murphy Wetland as well as the chemicals selected as COPCs based on comparison to residential soil RSLs. The maximum detected results for 29 contaminants exceed their respective residential soil RSLs and were selected as sediment COPCs.

The 29 sediment COPCs for the Murphy Wetland are summarized below:

Sediment COPCs – Murphy Wetland		
napththalene	dibenz(a,h)anthracene	iron
vinyl chloride	C11-C22 aromatics	lead
ethylene dibromide	C9-C18 aliphatics	manganese
ethylbenzene	chromium VI	mercury
carbazole	aluminum	thallium
benzo(a)anthracene	antimony	vanadium
benzo(b)fluoranthene	arsenic	total PCBs
benzo(k)fluoranthene	barium	PCB TEQ
benzo(a)pyrene	chromium III	gamma-chlordane
indeno(1,2,3-cd)pyrene	cobalt	

A similar list of sediment COPCs was identified in the 2006 baseline risk assessment since the same data set was used for this and the 2006 COPC selection process. Slight differences in the lists of COPCs are due to changes in RSL that have occurred since 2006.

COPCs in Soil Gas at the Commercial Buildings. Because contaminants with the potential to impact indoor air were detected in soil and groundwater near the current on-property commercial buildings, subslab soil gas sampling was conducted in 2010 beneath each of the on-property

buildings, except for the ice skating rink on the Aberjona property which was constructed with a vapor barrier as a precaution to mitigate a potential vapor intrusion pathway. Constituents detected in the subslab soil gas samples collected from beneath the on-property buildings are summarized in Table 3-2.6. Table 3-2.6 lists chemicals detected in subslab soil gas samples as well as the chemicals that exceed 10-times the industrial air RSLs (adjusted to a HQ of 0.1 for noncarcinogens), applicable to current commercial use of the buildings.

Of the three commercial properties, only the commercial building on the Aberjona property is considered "occupied" (i.e., workers present consistently for 8-hour shifts). Four VOCs exceed conservative subslab screening criteria at the Aberjona property, C5-C8 aliphatics, C9-C12 aliphatics, tetrachloroethene and trichloroethene. Three of the four compounds (C5-C8 aliphatics, C9-C12 aliphatics and trichloroethene) exceed their screening criteria by 2-fold or less, and tetrachloroethene exceeds its screening criteria by less than 10-fold. Because the screening criteria are set at either a $1x10^{-6}$ target risk level for potential carcinogens or a hazard quotient (HQ) of 0.1 for noncarcinogens, exceedances that are 10-fold less than the screening criteria would be associated with a cancer risk of less than $1x10^{-5}$ and a noncarcinogenic hazard of less than 1. Therefore, no further evaluation of the vapor intrusion pathway has been performed for the Aberjona property building. However, the future vapor intrusion pathway will require further evaluation if a change in usage of the existing commercial buildings is contemplated that would result in higher occupancy (e.g., daycare use of the building), or as part of new building construction including any addition to the existing building. Use of a vapor barrier or subslab system may be appropriate to mitigate the vapor intrusion pathway in instances of future development/construction of occupied buildings.

The Whitney building is primarily used for storage with workers present in the building only briefly at the beginning or end of each work day to pick up or drop off equipment and supplies or intermittently for longer periods of time (e.g., to periodically service, repair or inventory equipment). Six VOCs exceeded the soil gas screening criteria; three of the six VOCs (tetrachloroethene, cis-1,2-dichloroethene and trichloroethene) exceeded the screening criteria by 100-fold or more. Therefore, even though the current vapor intrusion pathway is incomplete due to current building usage as primarily for storage, the future vapor intrusion pathway will require

further evaluation if a change in usage of the existing commercial buildings is contemplated that would result in higher occupancy (e.g., full-time commercial use of the building), or as part of new building construction including any addition to the existing building. Use of a vapor barrier or subslab system may be appropriate to mitigate the vapor intrusion pathway in instances of future development/construction of occupied buildings.

The Murphy building is used primarily for equipment storage, with one small office space that is used for records storage and intermittent occupancy. One subslab soil gas sample was collected beneath the office space. Only one VOC (dichlorodifluoromethane) exceeded the soil gas screening criteria and the exceedance was less than 2-fold. Therefore, no further evaluation of the vapor intrusion pathway has been performed for the Murphy property building. However, the future vapor intrusion pathway will require further evaluation if a change in usage of the existing commercial buildings is contemplated that would result in higher occupancy (e.g., full-time commercial use of the building), or as part of new building construction including any addition to the existing building. Use of a vapor barrier or subslab system may be appropriate to mitigate the vapor intrusion pathway in instances of future development/construction of occupied buildings.

COPCs in Indoor Air at the Existing Aberjona Residence.

The list of indoor air COPCs at the existing Aberjona residence was developed using the screening process described below. Indoor air COPCs were selected using a two-step process: (1) a risk-based screening of concentrations of VOCs detected in indoor air and (2) an evidence-based screening of VOC detections in both shallow groundwater and subslab soil gas. The evidence-based screening was used to indicate that a VOC is present in indoor air as a result of the VI pathway rather than from an indoor source. The two-step COPC selection process is described in the following sections.

Risk-Based Screening. As previously described, the maximum detected concentration of each VOC in indoor air was compared to RSLs for residential air published by EPA in November 2013 (EPA, 2013a), based on an ILCR of $1x10^{-6}$ or a HQ of 0.1. Chemicals detected at

concentrations below their screening levels were eliminated from further evaluation. Comparisons of maximum concentrations to screening levels are presented in Appendix D, Table 2.

3.2.3.3 Evidence-Based Screening

Because indoor air may be impacted by many types of sources, including VI impacts from VOCs in groundwater migrating from the Southwest properties, the indoor use of VOC containing products and equipment, off-gassing from building materials and furnishings, and ambient outdoor air quality, selecting COPCs for indoor air needs to consider the following lines of evidence:

- The potential for site-related VOCs in groundwater to migrate to downgradient locations;
- Whether concentrations of site-related volatile groundwater compounds that have migrated downgradient of the Southwest properties are present at sufficient concentrations to impact soil gas beneath the existing Aberjona residence, and potentially impact indoor air quality within the building;
- The potential for indoor sources to contribute to concentrations of contaminants measured in indoor air;
- The concentrations of volatile compounds in upwind ambient outdoor air with the potential to impact indoor air quality; and
- The presence of potential breakdown products of chlorinated VOCs that may have been produced following migration of parent compounds from groundwater.

Figure 3-3 outlines the procedure used to determine indoor air COPCs at the existing Aberjona residence.

As the first step in the evidence-based COPC selection process, a comprehensive list of VOCs detected in groundwater at and downgradient of the Southwest properties was compiled using 2011 and 2013 groundwater investigation data (see Appendix A.2). This list of detected

groundwater VOCs provides the site-related VOCs that could potentially be considered indoor air COPCs at the existing Aberjona residence. If a VOC was not detected in groundwater, but was detected in indoor air at the existing Aberjona residence, then the finding is likely related to a source other than the Site. Compounds detected in groundwater include primarily chlorinated VOCs and petroleum-related compounds. The VOCs detected in groundwater from the Southwest properties are shown under the "Groundwater" column of Figure 3-3.

Subslab soil gas sampling data were then considered to assist in establishing whether a complete VI pathway exists between groundwater and indoor air. All of the compounds detected in subslab soil gas samples were also detected in groundwater samples, with exceedances of EPA soil gas screening levels (i.e., 10-times the residential air RSLs) identified, including chloroform, PCE and TCE (see Appendix A.5).

Any indoor air VOCs detected in both groundwater and subslab soil gas were selected as COPCs. VOCs that were not detected in both groundwater and subslab soil gas were considered unrelated to the Site, and not selected as COPCs. Figure 3-3 shows the evidence-based COPC selection for the existing Aberjona residence, with indoor air COPCs (present in both groundwater and subslab soil gas) highlighted in black. Naphthalene was included as an indoor air COPC, even though the subslab soil gas concentrations were significantly less than the indoor air concentrations, indicating that at least a portion of the naphthalene detected in indoor air is present as a result of an indoor source rather than the vapor intrusion pathway.

As a final step of the COPC selection process, the lists of indoor air COPCs were reviewed to assure that all breakdown products of the significant chlorinated site-related VOCs (PCE, TCE, and 1,1,1-trichloroethane) had been selected as indoor air COPCs, even if the compound was not detected in the subslab soil gas samples or in groundwater. PCE breakdown products include: TCE, cis- and trans-1,2-dichloroethene, 1,1-dichloroethene, and vinyl chloride; TCE breakdown products include: cis- and trans-1,2-dichloroethene, 1,1-dichloroethene, and vinyl chloride; and 1,1,1-trichloroethane breakdown products include: 1,1-dichloroethane, 1,1-dichloroethene, and vinyl chloride. None of these breakdown products had been omitted from the lists of potential COPCs for the evidence-based screening.

Detections of VOCs in upwind ambient outdoor air samples are also included in Figure 3-3. Though these results are not used in the COPC screening process, the ambient outdoor air sampling results may be used to frame the risk characterization results, as necessary. Indoor air COPCs for the existing Aberjona residence, considering both the risk-based and evidence-based screening, are presented in Appendix D, Table 2.

3.2.4 Determination of Exposure Point Concentrations

To evaluate the magnitude of potential human exposures, the concentration of each COPC in each exposure medium must be estimated. An estimate of this concentration is referred to as an EPC. EPCs were determined for the COPCs in each medium for each exposure point.

EPA recommends calculation of the 95% UCL on the arithmetic mean concentration for the estimation of both the CTE and RME risk (EPA, 1989; 1992). Therefore, whenever possible, the 95% UCL has been calculated and used as the EPC for both the RME and CTE cases. The 95% UCLs were calculated using EPA's program ProUCL Statistical Software (EPA, 2011a; 2013b). The 95% UCL values if a sufficient number of samples were available from an exposure point. When an insufficient number of samples were available, the program was typically unable to calculate a reliable 95% UCL value.

Appendix B.5 contains documentation for the calculation and selection of the 95% UCL values.

For small data sets (typically less than nine samples), the maximum detected COPC concentration was used as the EPC for the RME case and the arithmetic mean concentration was used as the EPC for the CTE case. For the indoor air evaluation at the existing Aberjona residence, maximum detected COPC concentrations were used as EPCs for both the RME and CTE cases. When the 95% UCL value for a COPC exceeded the maximum detected concentration because of small sample sizes or high data set variability, the maximum detected COPC concentration was used as the EPC for the RME scenario, and the arithmetic mean value was used as the EPC for the CTE case (EPA, 1989; 1992). In cases where the arithmetic mean

value exceeded the maximum detected COPC concentration, which is possible in situations where the data includes slightly elevated non-detect concentration values, the maximum detected COPC concentration was used as the EPC for both the RME and CTE cases.

Surface Soil. For surface soil, each of the three Southwest Properties (Aberjona, Whitney and Murphy properties) were quantitatively evaluated as separate exposure points using COPCs that were selected using soil data from the three properties (see Table 3-2.1). For current scenarios, Tables 3-3.1 RME and 3-3.1 CTE list the surface soil COPCs detected along with the EPCs determined for the RME and CTE scenarios, respectively. Tables 3-3.2 RME and 3-3.2 CTE list the surface soil COPCs detected along with the EPCs determined for the future case RME and CTE scenarios, respectively.

Subsurface Soil. Subsurface soil was evaluated for the future scenario under the assumption that Site development results in the disturbance and movement of soils to a location where exposures may occur. Subsurface soil data from each of the three Southwest Properties were quantitatively evaluated as separate exposure points using COPCs that were selected using subsurface soil data (2-15 feet) from the three properties (see Table 3-2.1). Tables 3-3.3 RME and 3-3.3 CTE list the subsurface soil COPCs detected along with the EPCs determined for the future case RME and CTE scenarios, respectively.

Groundwater. Exposure to groundwater was evaluated for future scenarios. Groundwater data collected from each of the Southwest Properties (Aberjona, Whitney and Murphy properties) were quantitatively evaluated using COPCs that were selected using the 2011 and 2013 groundwater data combined (see Table 3-2.2). For the future scenario, Tables 3-3.4 RME and 3-3.4 CTE list the groundwater COPCs detected along with the EPCs determined for the RME and CTE site-wide residential groundwater use scenarios, respectively. Tables 3-3.5 RME and 3-3.5 CTE list the property-specific shallow groundwater COPCs detected and EPCs determined for future RME and CTE scenarios, respectively, for the construction worker scenario at each property. Arithmetic mean and maximum detected values have been used in the estimation of risk for the site-wide residential groundwater use scenario. 95% UCLs have been calculated for the property-specific construction worker direct contact scenario, if possible.

Surface Water. Exposures to surface water were evaluated for both the current and future scenarios. For surface water, the risk assessment quantitatively evaluates only one human health exposure point (i.e., the Murphy Wetland). COPCs were selected using unfiltered 2002 data (see Table 3-2.3). For current and future scenarios, Tables 3-3.6 RME and 3-3.6 CTE list the surface water COPCs detected and the EPCs determined for the RME and CTE scenarios, respectively. Since only three surface water samples were collected from the Murphy Wetland, 95% UCL values were not calculated. Thus, the maximum detected concentrations and arithmetic mean concentrations were used as EPCs for the RME and CTE scenarios.

Sediment. Exposures to sediment were evaluated for both the current and future scenarios. For sediment, as with surface water, the risk assessment quantitatively evaluates only one exposure point (i.e., the Murphy Wetland). COPCs were selected using all sediment data combined (see Table 3.2-4). For the current and future exposure scenarios, Tables 3-3.7 RME and 3-3.7 CTE list the sediment COPCs detected and the EPCs determined for the RME and CTE scenarios, respectively. The 95 % UCL values have been provided because more than nine sediment samples were collected from the wetland.

Outdoor Trench Air. Soil and groundwater data from Southwest Properties were quantitatively evaluated for outdoor trench air impacts. Only those compounds detected in soil with Henry's Law constants greater than 1E-05 atm-m^3/mole and molecular weights less than 200 grams/mole (EPA, 1991a) were used to model outdoor trench air concentrations (see Appendix B.3) and select outdoor trench air COPCs (see subsection 3.2.3.2).

Tables 3-3.8 RME and 3-3.8 CTE list the outdoor trench air COPCs along with the modeled EPC for the RME and CTE scenarios, respectively, for impacts from soil. Tables 3-3.9 RME and 3-3.9 CTE list the air COPCs along with the modeled EPCs for the RME and CTE scenarios, respectively, for impacts from groundwater.

Indoor Air. Exposures to indoor air at the existing Aberjona residence were evaluated for both current and future scenarios. COPCs were selected considering groundwater, subslab soil gas

and indoor air data using both risk-based and evidence-based screening processes (see Figure 3-3 and Appendix D, Table 2). For the current and future exposure scenarios, Appendix D, Tables 3.1 RME and CTE and 3.2 RME and CTE list the indoor air COPCs detected and the EPCs determined for the RME and CTE scenarios, respectively. Maximum detected concentration in the first floor samples were used as current EPCs; maximum detected concentrations in the basement and first floor samples combined were used as future EPCs.

3.3 Exposure Assessment

The purpose of the exposure assessment is the quantification of the extent, frequency and duration of actual or potential exposure to chemicals by pathways relevant to the Site and activities of the potential receptors.

3.3.1 Identification of Potentially Exposed Populations and Potential Exposure Pathways

As part of the exposure assessment, current and potential future exposure pathways were determined through which identified populations may be exposed to the COPCs at the Southwest Properties. A historical account and physical description of the Southwest Properties can be found in Section 1.

An exposure pathway describes the course a chemical follows while moving through environmental media to a receptor. An exposure pathway may consist of a mechanism of release of contaminants to an environmental medium (e.g., soil), an exposure route (e.g., ingestion) and a receptor (e.g., trespasser). An exposure pathway is considered complete when contact by a receptor with contaminated media may occur currently or in the future. For purposes of this risk assessment, only potentially complete exposure pathways were quantitatively evaluated.

EPA (1989 and 1991b) guidance requires that plausible exposures under both current and future land-use scenarios be evaluated in a baseline risk assessment. Accordingly, potential human exposure pathways were identified for both current and potential future land-use scenarios at the Site. The current land-use scenario examines the potential for human exposure under current site

conditions, while the future land-use scenario evaluates potential exposures following possible changes in site land use (assuming no remedial action occurs).

3.3.1.1 Potential Exposure Pathways and Receptors Under Current Land Use Conditions

The Site consists of three properties (Aberjona, Whitney, and Murphy properties). Current land use is commercial/industrial at all three sites, except for an existing residence at the Aberjona property. The Southwest Properties are zoned industrial (City of Woburn, 2012). Properties surrounding the Site are also zoned industrial. Portions of each of the properties are in the mapped 100-year floodplain. Many of the on-site areas of known contamination are currently fenced and/or paved. Commercial workers may access these secured areas. A complete exposure pathway does not currently exist for the paved portions of the properties. Table 3-1 presents a summary of the current exposure routes qualitatively and quantitatively evaluated in the baseline risk assessment as well as the exposure points and receptors. The following justifies the selection or exclusion of exposure points, receptors and exposure routes under current land-use conditions.

Resident. There is an occupied residence located on the Aberjona property. Floodplain soils and sediments in the backyard of this residence were previously evaluated (EPA, 2004a and 2005a). However, the residents may be exposed to contaminants in indoor air via inhalation as a result of a potentially complete vapor intrusion pathway associated with shallow groundwater VOC contamination. Because there are no known potable wells on-site or in the vicinity of the Site, current residential exposures to groundwater used as household water are not addressed.

Commercial Worker. Adult commercial workers are present at all three of the Southwest Properties. Contact with exposed surface soils in unpaved portions of the properties may occur as part of job-related activities. Potential exposure routes for contaminated surface soil include incidental ingestion and dermal contact. Inhalation of contaminants in fugitive dust is expected to be negligible since these workers are not performing invasive activities. As previously discussed, the vapor intrusion pathway has not been quantitatively evaluated due to low concentrations of VOCs in soil gas or the lack of occupied use of the current buildings.

On the Murphy and Whitney properties, commercial operations would result in little, if any, contact by human receptors with surface water and sediment of the Murphy Wetland; therefore the exposure of commercial workers to these media was not quantitatively evaluated. The evaluation of the trespasser (see below) is likely to be a conservative representation of commercial exposures, should they be occurring.

Trespasser. Many of the known contaminated areas are either secured by fencing or below pavement. Consequently, exposure pathways involving trespassers (older children) and contaminated surface soil (0 to 2 feet) are limited to the Whitney property where the gate is frequently left unsecured. Trespasser exposure to contaminated Murphy Wetland surface water and sediment were also evaluated since the wetland is accessible to trespassing through the unsecured Whitney property. Due to the presence of shallow surface waters, wading in likely to be the primary activity in the wetland.

The exposure routes quantitatively evaluated for trespassers include incidental ingestion of and dermal contact with contaminated surface soil. For surface water, only dermal exposures are evaluated. Ingestion of surface water for wading-related exposures was not assessed since it is unlikely that a wader would ingest more than a negligible amount of surface water. For sediment, the exposure pathways include incidental ingestion and dermal contact.

3.3.1.2 Potential Exposure Pathways and Receptors Under Future Land Use Conditions

Table 3-1 presents a summary of the future exposure routes quantitatively and qualitatively evaluated in the baseline risk assessment along with the exposure points and receptors. To evaluate potential future exposures, it was assumed that no remedial action was taken, and that the levels of contamination currently existing at the Site would remain the same in the future. However, since future activities on-site may result in the removal of pavement and access obstacles, future receptors (e.g., trespassers) are assumed to be exposed to accessible as well as currently inaccessible surface soil throughout the properties. Since future activities on-site may also result in the movement of soils currently at depth to the surface, certain future receptors are

also assumed to be exposed to subsurface soil (2 to 15 feet below ground surface) as well as surface soil (e.g., recreational visitors).

For the purposes of this baseline risk assessment, the exposures described under current land-use conditions for the existing Aberjona resident and commercial workers may remain unchanged in the future, except that worker exposures may occur to surface soils that are currently paved, assuming the pavement is removed or falls into disrepair in the future. Future trespasser exposures may also occur. However, it is assumed that the properties may become more accessible by the removal of current access obstacles (paving, fencing, locked gates). Based on potential redevelopment plans for the Site, it was also assumed that land use may change at the Southwest Properties, resulting in the construction of recreational facilities. Consequently, future recreational use of the Southwest Properties is included in this evaluation. Given the potential for the construction of new commercial or recreational facilities, a construction worker scenario has also been included. Should a change in land use at the Southwest Properties be contemplated that would include activities and uses not evaluated in the risk assessment, further evaluation will be required to assess the risks associated with the proposed land use change, including use of groundwater for purposes not identified in the risk assessment.

The following justifies the selection or exclusion of exposure points, receptors and exposure routes under assumed future land-use conditions.

Resident. Further residential development of the Aberjona, Murphy and Whitney properties is considered highly unlikely in the future because the site and surrounding area are zoned industrially and are highly commercial/industrial, and portions of each of the properties are within the mapped 100-year floodplain, making them uninviting for further residential development. Therefore, residential exposure to surface or subsurface soil is not evaluated. However, young child exposure to soils is evaluated as part of the future recreational scenario. The existing residence on the Aberjona property is assumed to remain as such in the future. Therefore, the future vapor intrusion pathway has been evaluated for residents of this building.

Because Site groundwater is categorized as a potentially productive area (i.e., GW-1 category) by MassDEP (2004), a future residential groundwater use scenario has been included. Exposure to contaminated groundwater will be addressed on a site-wide basis for the hypothetical future residential population, in contrast to the property-by-property approach used for the construction worker scenarios. This approach is based on the assumption that groundwater, as a mobile medium, can be drawn to a property by pumping, or can migrate to another property under natural gradients. Consequently, a future resident could be exposed to contaminated groundwater from all three of the properties with equal likelihood. Exposures to contaminated groundwater for adult and young child (i.e., 1 to 6 years old) residents are through the routes of ingestion, dermal contact, and inhalation assuming tap water consumption and water contact during showering and bathing, laundry, dish washing and other household activities.

Commercial Worker. In the future, commercial use is assumed to continue at all three of the Southwest Properties. Potential commercial workers exposures evaluated in the risk assessment include surface soil incidental ingestion and dermal contact. Inhalation of contaminated fugitive dust is expected to be negligible since commercial workers are not assumed to perform invasive activities. Subsurface soil exposures are not evaluated for commercial receptors since commercial land use may continue into the future without soil disturbance. However, exposure to surface soil locations that are currently covered with pavement are evaluated, assuming the pavement falls into disrepair in the future. Should soils at depth be disturbed in the future by construction/excavation, the disturbance is likely to be short-term and pavement is likely to be placed upon completion of the work, thus limiting commercial exposures to subsurface contaminants.

Trespasser. Contaminated surface soil on properties that are currently fenced is considered accessible in the future, including currently paved locations. Consequently, future older child trespassers are assumed to be exposed to contaminated surface soil via incidental ingestion and dermal contact at all three Southwest Properties. Subsurface soil exposures are not evaluated since current land use may continue into the future without soil disturbance. Should soils at depth be disturbed in the future by excavation, the disturbance is likely to be short-term and

pavement is likely to be placed upon completion of the work, thus limiting trespasser exposures to subsurface contaminants.

Exposure of the trespasser to contaminated surface water and sediment in the Murphy Wetland is also quantitatively evaluated. As in the current timeframe, exposure to surface water is assumed to occur through dermal contact only and exposure to sediment by both incidental ingestion and dermal contact.

Recreational Users. Each of the properties may be developed as recreational facilities. Recreational users are assumed to include adults and young children (i.e., 1 to 6 years old). Exposure pathways evaluated for recreational use include incidental ingestion of and dermal contact with contaminated soil at all three properties. Future recreational land use will require extensive reworking of the land with the possible movement of subsurface contamination to the surface. In addition, future recreational land use may not require extensive paving of the surface, therefore longer term exposure to subsurface soils will be possible. Hence, future recreational receptors are likely to be exposed to both surface and subsurface soil contamination. Contact with contaminated surface water and sediment in the Murphy Wetland is also possible for the recreational user via a wading scenario. Future exposure pathways evaluated for recreational use include incidental ingestion of, and dermal contact with, contaminated sediments, and dermal contact with contaminated surface water during wading.

Construction Worker. Since changes in land use may occur, it is reasonable to assume that construction workers may be exposed to contaminants in soil and shallow groundwater during the construction of new facilities or installation of utility connections. Construction work is assumed for all three of the Southwest Properties. Future construction workers may be exposed to surface and subsurface soils through incidental ingestion and dermal contact. Inhalation of contaminated fugitive dust is expected to be potentially significant due to the types of invasive activities being performed and has been evaluated on a quantitative basis. Future exposure to property-specific groundwater includes incidental ingestion of, and dermal contact with, contaminated groundwater during dewatering operations. Construction workers are likely to contact shallow groundwater only (0 to 15 feet below ground surface).

Construction workers may also be exposed to fugitive contaminant vapors (i.e., outdoor trench air) that migrate to the air space of construction excavations. Exposure to impacted outdoor trench air attributable to contaminated groundwater and soil is quantitatively evaluated for the Whitney property only, as no outdoor trench air COPCs were selected for the Aberjona and Murphy properties.

3.3.1.3 Summary of Pathways and Receptors Selected for Consideration

The following items summarize the pathways quantitatively evaluated for each exposure scenario. Outdoor trench air impacts attributable to soil are identified with an "(s)" and outdoor trench air impacts attributable to groundwater are identified with a "(gw)". The use of the term "Southwest Properties" in this subsection is meant to indicate each of the three properties (Aberjona, Whitney, and Murphy properties) for the purposes of the following summary, otherwise the properties are cited individually. Exceptions are noted where warranted. Please refer to Table 3-1, which summarizes scenarios addressed quantitatively and qualitatively, provides assumptions related to media depth, and presents the rationale for the selection or exclusion of exposure pathways.

- **Residential scenario, existing Aberjona residence, current/future**

  Inhalation pathway: Indoor air (vapor intrusion)

- **Residential scenario, Site-Wide, future**

  Ingestion pathway: Groundwater (site-wide)
  Inhalation pathway: Groundwater (site-wide)
  Dermal contact pathway: Groundwater (site-wide)

- **Commercial worker scenario, Southwest Properties, current/future**

  Ingestion pathway: Surface soil
  Dermal contact pathway: Surface soil

- **Trespasser, Whitney Property, current**

  Ingestion pathway: Surface soil

  Dermal contact pathway: Surface soil

- **Trespasser, Southwest Properties, future**

  Ingestion pathway: Surface soil

  Dermal contact pathway: Surface soil

- **Trespasser, Murphy Wetland, current/future**

  Ingestion pathway: Sediment

  Dermal contact pathway: Surface water, sediment

- **Recreational user scenario, Southwest Properties, future**

  Ingestion pathway: Surface and subsurface soil

  Dermal contact pathway: Surface and subsurface soil

- **Recreational user scenario, Murphy Wetlands, future**

  Ingestion pathway: Sediment

  Dermal contact pathway: Surface water, sediment

- **Construction worker scenario, Southwest Properties (property-specific), future**

  Ingestion pathway: Surface and subsurface soil, shallow groundwater

  Inhalation pathway: Outdoor trench air (s) (Whitney property)

  Outdoor trench air (gw) (Whitney property)

  Fugitive dust

  Dermal contact pathway: Surface and subsurface soil, shallow groundwater

This risk assessment incorporated the results of the site-specific relative bioavailability study performed for the Aberjona River Study Baseline Risk Assessment (EPA, 2004a). Sediment used in the study was collected across the wetland and riverine areas through the Aberjona River Study Area. The bioavailability study was done to decrease the uncertainty associated with ingestion of arsenic-containing sediment. The study involved the feeding of arsenic to swine in a sediment matrix. The oral absorption of arsenic from sediment matrix was quantified and determined to be less than the absorption of arsenic from a water medium. The most conservative relative bioavailability estimate from the study was then used in the human health risk assessment to more accurately characterize the risk associated with sediment ingestion at the Site. The most conservative relative bioavailability estimate and the Aberjona River Study Baseline Risk Assessment Report were also referenced in the Draft Final, MSGRP Remedial Investigation Report, Industri-Plex Superfund Site, Operable Unit 2, Woburn, Massachusetts (EPA, 2005a). Though sediment was not collected from the Murphy Wetland for the arsenic bioavailability study, sediment for use in the study was collected from wetlands adjacent to and hydraulically connected to the Murphy Wetland. Therefore, use of the most conservative relative bioavailability estimate from the study is likely to be conservatively representative of sediment in the Murphy Wetland.

3.3.2 Calculation of Dose

Part of the exposure assessment is to identify exposure equations to be used in the risk assessment and to document assumptions made for each of the parameters used in these equations. The selection of exposure equations and assumptions is based both on available guidance and professional judgment.

Both CTE and RME estimates of exposure have been quantified in this risk assessment. The risk assessment used the default CTE parameters to evaluate average exposures and RME parameters to evaluate high-end exposures. EPA guidance or documents used in the exposure assessment include *RAGS, Part A* (EPA, 1989); *Exposure Factors Handbook* (EPA, 2011b); *RAGS, Part E Supplemental Guidance for Dermal Risk Assessment* (EPA, 2004b), *Supplemental Soil Screening*

Guidance (EPA, 2002c) and *OSWER Directive 9285.6-03, Standard Default Exposure Parameters* (EPA, 1991c).

3.3.2.1 Selection of Exposure Equations

Tables 3-4.1 through 3-4.10 provide the medium-specific equations used for the calculation of carcinogenic and noncarcinogenic chronic daily intake (CDI) values. For the vapor intrusion indoor air pathway at the existing Aberjona residence, the equations are presented in Appendix D, Table 4.1. The equations are used for calculating a lifetime average daily dose (LADD) relevant to cancer risk (i.e., cancer intake) or for calculating an average daily dose (ADD) relevant to noncancer risk (i.e., noncancer intake). Additional equations used in calculating dose following inhalation and dermal exposures in site media are contained in Appendices B.3 (outdoor trench air modeling) and B.4 (dermal water calculations), respectively.

3.3.2.2 Exposure Parameters

The exposure parameters used for each of the receptors evaluated in the risk assessment are described below and are presented in Tables 3-4.1 through 3-4.10, and in Appendix D, Table 4.1, for the vapor intrusion indoor air pathway at the existing Aberjona residence. Since exposure parameters vary depending on the exposure pathway and receptor being evaluated, the exposure parameters are presented by pathway in the tables and are discussed by receptor.

Commercial Worker Exposure Parameters. The exposure parameters for the adult commercial worker are shown in Tables 3-4.1 (surface soil, current land use) and 3-4.2 (surface soil, future land use). These exposure parameters rely partially on default CTE and RME parameters presented in *OSWER Directive 9285.6-03,Standard Default Exposure Parameters* (EPA, 1991c) and *RAGS, Part E Supplemental Guidance for Dermal Risk Assessment* (EPA, 2004b).

For the soil ingestion pathway, the default CTE and RME soil ingestion rate of 100 mg/day was used (EPA, 2002c). This ingestion rate is the recommended value for an adult in an industrial

setting. It was assumed that commercial workers may be exposed to soil for 125 days/year for both the RME and CTE cases based on professional judgment. This exposure frequency represents 5 days of exposure each week for the warmest 6 months of the year. Soil exposures during the colder months when the ground is frozen or covered by snow have not been assumed to occur.

The default high-end exposure duration of 25 years was used for the RME case, while an average exposure duration of 9 years was used for the CTE case (EPA, 2004b). The default value of 70 kg for an adult body weight was used for both CTE and RME cases (EPA, 1991c). As recommended in RAGS (EPA 1989), the averaging time for non-carcinogens was set equal to the exposure duration, and the averaging time for carcinogens was the standard EPA lifetime duration (70 years).

For the soil dermal pathway, skin surface areas were calculated for the body parts that could contact soil, using statistical distributions of surface areas provided in *RAGS, Part E Supplemental Guidance for Dermal Risk Assessment* (EPA, 2004b). Commercial workers were assumed to contact soils with 3,300 cm^2 of body surface area for both the CTE and RME cases (50^{th} percentile value; EPA, 2004b). This surface area assumes exposure to the head, hands and forearms. A weighted soil-to-skin adherence factor of 0.2 mg/cm^2-day was used for both the CTE and RME cases (95^{th} percentile value; EPA, 2004b), consistent with landscapers and gardeners, an activity selected to represent a conservative high end activity for an adult commercial work at the site.

Dermal absorption factors provided in Exhibit 3-4 of *RAGS, Part E Supplemental Guidance for Dermal Risk Assessment* (EPA, 2004b) were used to evaluate risk associated with dermal contact with soil. Dermal absorption factors of 3% (arsenic), 0.1% (cadmium), 4% (chlordane), 3% (DDT), 3% (TCDD TEQ), 13% (benzo(a)pyrene and other PAHs), 14% (Aroclors and other PCBs), and 10% (SVOCs) were used in both the RME and CTE cases. In the absence of recommended dermal absorption factors, dermal exposure to the remaining soil COPCs was not assessed as recommended by EPA (EPA, 2004b). The remaining exposure parameters used for the dermal exposure pathway (i.e., exposure frequency, exposure duration, body weight, and

averaging time) were the same as the values described for the soil ingestion pathway for this receptor.

Trespasser Exposure Parameters. The exposure parameters for the trespasser, assumed to be an older child (12 to 18 years of age), are shown on Table 3-4.1 (surface soil, current land use), Table 3-4.2 (surface soil, future land use), Table 3-4.7 (surface water, current land use), Table 3-4.8 (surface water, future land use), Table 3-4.9 (sediment, current land use), and Table 3-4.10 (sediment, future land use). These exposure parameters rely partially on default CTE and RME exposure parameters presented in the *OSWER Directive 9285.6-03,Standard Default Exposure Parameters* (EPA, 1991c), the *Exposure Factors Handbook* (EPA, 2011b) and *RAGS, Part E Supplemental Guidance for Dermal Risk Assessment* (EPA, 2004b).

The climate at Site is not conducive to outdoor activities for about 6 months of the year. Under this assumption, the older child trespasser may venture onto the Site 1 to 2 days per week for the warmest 6 months of the year (26 to 52 days/year). It was assumed that the current trespasser may venture onto the site and engage in activities resulting in soil, sediment and surface water exposures 26 days/year for both the CTE and RME cases. Exposure frequency values under future land are 26 days/year for CTE and 52 days/year for RME. The increased frequency under future land use assumes that access obstacles are removed in the future resulting in increased accessibility to trespassers.

The fraction of sediment ingested was assumed to be 50% for both the CTE and RME cases. Use of a fraction-ingested term assumes that a receptor ingests a portion of the daily sediment/soil intake from the Site and a portion from wetland/upland areas not impacted by the Site (i.e., background areas). This assumption is consistent with the approach used for the Industri-Plex OU-2/Wells G&H OU-3 River Study risk assessment (EPA, 2004a and 2005a),.

For the soil and sediment ingestion pathways, the default CTE and RME soil ingestion rates (50 mg/kg and 100 mg/kg, respectively; EPA, 2011b; 1991c) for adult residents were used since older children will likely ingest similar quantities to those ingested by adults. Surface water

exposure time was set at 0.5 hour/event and 1 hour/event for the CTE and RME case, respectively.

Exposure duration is assumed to be 2 years for the CTE case and 6 years for the RME case (professional judgment). The value of 57 kg for the body weight of an older child was used for both CTE and RME exposures (EPA, 2011b). The averaging time for non-carcinogens was set equal to the exposure duration, and the averaging time for carcinogens was the standard EPA lifetime duration (70 years; EPA, 1989).

For the dermal pathway, skin surfaces were calculated for the body parts that could contact surface soil, sediment and surface water, using statistical distributions of surface areas provided in *RAGS, Part E Supplemental Guidance for Dermal Risk Assessment* (EPA, 2004b). The trespasser is assumed to contact environmental media with 4,500 cm^2 of body surface area for both the RME and CTE cases (EPA, 2004b). This surface area assumes exposure to face, forearms, hands and lower legs. A soil-to-skin adherence factor of 0.2 mg/cm^2-day was used for both the CTE and RME cases (approximate 95^{th} percentile value; EPA, 2004b). This value is a 50^{th} percentile weighted value for children playing in wet soil, an activity selected to represent a reasonable high-end activity for an older child trespasser. The same surface area and soil-to-skin adherence factors selected for soil have also been used for sediment since EPA suggests using the same approach for sediment as that used for soil (EPA, 2004b).

Dermal absorption factors provided in Exhibit 3-4 of *RAGS, Part E Supplemental Guidance for Dermal Risk Assessment* (EPA, 2004b) were used to evaluate risk associated with dermal contact with soil and sediment. In the absence of recommended dermal absorption factors, dermal exposure to the remaining soil and sediment COPCs was not assessed as recommended by EPA (EPA, 2004b).

The remaining exposure parameters used for the dermal exposure pathway (i.e., exposure frequency, exposure duration, body weight, and averaging time) were the same values described for the ingestion pathways.

Resident Exposure Parameters. The exposure parameters for the adult and child resident are shown in Table 3-4.5 for the site-wide tap water pathway (groundwater, water exposures during household use, future land use) and in Appendix D, Table 4.1, for the vapor intrusion indoor air pathway. These exposure parameters rely partially on default CTE and RME exposure parameters presented in *OSWER Directive 9285.6-03,Standard Default Exposure Parameters* (EPA 1991c) and *RAGS, Part E Supplemental Guidance for Dermal Risk Assessment* (EPA, 2004b).

Due to the GW-1 classification of Site groundwater, ingestion of, dermal contact with, and inhalation of VOCs from contaminated groundwater are evaluated under a site-wide future residential scenario.

For the site-wide future groundwater ingestion pathway, adult CTE and RME ingestion rates of 1.4 liters/day and 2.0 liters/day, respectively, were used (EPA, 1991c; 1997a). For the young child, CTE and RME ingestion rates of 0.87 liters/day and 1.0 liters/day, respectively, were used (EPA, 1997a; 1989). Exposures were assumed to occur 350 days/year in both the CTE and RME cases (EPA, 2004b). This value assumed that residents are away from the home (e.g., on vacation) for two weeks of the year.

For the site-wide future adult, the default high-end exposure duration of 24 years was used for the RME case, while an average exposure duration of 7 years was used for the CTE case (EPA, 2004b). The default value of 70 kg for an adult body weight was used for both CTE and RME cases (EPA, 1991c). For the young child, a high-end exposure duration of 6 years was used for the RME case, while an average exposure duration of 2 years was used for the CTE case (EPA, 2004b). The default value of 15 kg for young child body weight was used for both CTE and RME cases (EPA, 1991c). For both adult and young child, the averaging time for non-carcinogens was set equal to the exposure duration, and the averaging time for carcinogens was the standard EPA lifetime duration (70 years).

The Andelman model is used to estimate vapor concentrations that may occur as a result of future household uses of water, such as bathing, showering, laundry and dish washing. The

output of the Andelman model can be simplified to a constant of 0.5 L/m^3 (EPA, 1991a; 2012b). This constant is used with the groundwater EPCs for volatile COPCs only to derive an indoor air concentration. Residents are assumed to be exposed to the VOC impacted air for 24 hours/ day for both the RME and CTE cases (EPA, 1991a). The remaining exposure parameters used for the inhalation exposure pathway (i.e., exposure frequency, exposure duration and averaging time) were the same as the values described for the groundwater ingestion pathway discussed above.

For the dermal pathway, skin surface areas were selected for the body parts that could contact contaminated groundwater water while showering, using statistical distributions of surface areas provided in *RAGS, Part E Supplemental Guidance for Dermal Risk Assessment* (EPA, 2004b). The adult resident was assumed to contact groundwater during showering with 18,000 cm^2 of body surface area for both the CTE and RME cases (EPA, 2004b). The young child resident was assumed to contact groundwater during showering with 6600 cm^2 of body surface area for both the CTE and RME cases (EPA, 2004b). These surface areas assume exposure to the whole body. For the dermal exposure pathway, absorbed doses were calculated for each chemical using equations and chemical-specific factors provided by EPA (2004b). The dermal absorbed dose was calculated using chemical-specific permeability coefficients and, for organic compounds, molecular weight and octanol-water partition coefficients, as detailed in Appendix B.4 (Dermal Appendix). For this exposure, event times of 0.58 hours were assumed for both the CTE and RME cases (EPA, 2004b). This event time includes time in the shower as well as time after showering when the skin remains damp and absorption of contaminants through the skin continues. The remaining exposure parameters used for the dermal exposure pathway (i.e., exposure frequency, exposure duration, body weight and averaging time) were the same as the values described for the groundwater ingestion pathway discussed above.

For the adult and child resident at the existing Aberjona residence, the exposure time was assumed to be 24 hours per day for the RME scenario (EPA, 2011b) and 16 hours per day for the CTE scenario (EPA, 2011b). It was assumed that adult and child residents are exposed to indoor air for 350 days/year (50 weeks) for both the RME and CTE cases (EPA, 2004b). The exposure durations of 24 years and 6 years, respectively, were used for the RME adult and child, while

exposure durations of 7 years and 2 years, respectively, were used for the CTE adult and child (EPA, 2004b). The averaging time for non-carcinogens was set equal to the exposure duration, and the averaging time for carcinogens was the standard EPA lifetime duration (70 years).

Recreational User Exposure Parameters. The exposure parameters for the adult and child recreational user are shown in Table 3-4.2 (surface soil, future land use), Table 3-4.3 (subsurface soil, future land use), Table 3-4.8 (surface water; future land use), and Table 3-4.10 (sediment, future land use). These exposure parameters rely partially on default CT and RME exposure parameters presented in *OSWER Directive 9285.6-03,Standard Default Exposure Parameters* (EPA, 1991c) and *RAGS, Part E Supplemental Guidance for Dermal Risk Assessment* (EPA, 2004b).

As previously mentioned, the weather at the Site is not conducive to outdoor activities for about 6 months of the year. Therefore, it was assumed that the adult and young child recreational user may venture onto the site and engage in activities resulting in surface water, sediment, surface soil and subsurface soil exposure for 1 to 3 days per week for the warmest 6 months of the year. The exposure frequency values used for the CTE and RME cases for sediment, soil and surface water exposures were 1 or 3 days per week for the warmest 6 months of the year (i.e., 26 and 78 days/year), respectively.

For surface water, incidental ingestion was assumed to not occur during wading. For the soil and sediment ingestion pathways, the default CTE and RME soil ingestion rates (50 mg/kg and 100 mg/kg, respectively; EPA, 2011b; 1991c) for adult residents were used. For the sediment and surface soil ingestion pathway, the default CTE and RME soil ingestion rates (100 mg/kg and 200 mg/kg, respectively; EPA, 2011b; 1991c) for young child residents were used. Use of these values provides a conservative evaluation of soil and sediment exposure in a recreational setting. The fraction of sediment ingested from the Southwest Properties was assumed to be 50% for both the CTE and RME cases. Use of a fraction-ingested term for sediment is consistent with the approach used for the Industri-Plex OU-2/Wells G&H OU-3 River Study risk assessment (EPA, 2004a and 2005a).

For the dermal pathway, skin surface areas were selected for the body parts that could contact surface water, sediment or soil, using statistical distributions of surface areas provided in *RAGS, Part E Supplemental Guidance for Dermal Risk Assessment* (EPA, 2004b). Adult recreational users were assumed to contact sediments, surface soils and surface water during wading with 5,700 cm^2 of body surface area for both the CTE and RME cases (50^{th} percentile value; EPA, 2004b). The surface area assumes exposure to the face, forearms, hands and lower legs. A soil-to-skin adherence factor of 0.07 mg/cm^2-day was used for both the CTE and RME cases (EPA 2004b). This value is a 50^{th} percentile weighted adherence factor for gardeners, the activity selected to represent a reasonable high-end activity for the adult. Young child recreational users were assumed to contact sediments, soils and surface water during wading also with 2,800 cm^2 of body surface area for both the CTE and RME cases (50^{th} percentile value; EPA, 2004b). The surface area assumes exposure to the face, forearms, hands, lower legs and feet of the young child. A soil-to-skin adherence factor of 0.2 mg/cm^2-day was used for both the CTE and RME cases (EPA, 2004b). This value is a 50^{th} percentile weighted adherence factor for children playing in wet soil, the activity selected to represent a reasonable high-end activity for the child. The same surface area and soil-to-skin adherence factors selected for soil have also been used for sediment since EPA suggests using the same approach for sediment as that used for soil (EPA, 2004b).

Dermal absorption factors provided in Exhibit 3-4 of *RAGS, Part E Supplemental Guidance for Dermal Risk Assessment* (EPA, 2004b) were used to evaluate risk associated with dermal contact with soil. In the absence of recommended dermal absorption factors, dermal exposure to the remaining soil COPCs was not assessed as recommended by EPA (EPA, 2004b).

For the surface water dermal exposure pathway, absorbed doses were calculated for each chemical using equations and chemical-specific factors provided by EPA (2004b). The dermal absorbed dose was calculated using chemical-specific permeability coefficients and, for organic compounds, molecular weight and octanol-water partition coefficients, as detailed in Appendix B.4 (Dermal Appendix). For this exposure, event times of 0.5 hours and 1 hour were assumed for the CTE and RME cases, respectively, based on professional judgment. The remaining exposure parameters used for the dermal exposure pathway (i.e., exposure frequency,

exposure duration, body weight and averaging time) were the same as the values described for the soil and sediment ingestion pathways.

For the adult, the default high-end exposure duration of 24 years was used for the RME case (EPA, 1991c). For the CTE case, 7 years was selected as the average exposure duration (EPA, 2004b). The default value of 70 kg for an adult body weight was used for both CTE and RME cases (EPA, 1991c). For the young child, the default high-end exposure duration of 6 years was used for the RME case, while an average exposure duration of 2 years was used for the CTE case (EPA, 1991c; 2004b). The value of 15 kg for a young child body weight was used for both CTE and RME cases (EPA, 1991c). Finally, as recommended in *RAGS* (EPA 1989), the averaging time for non-carcinogens was set equal to the exposure duration, and the averaging time for carcinogens was the standard EPA lifetime duration (70 years) for both adult and young child residents.

Construction Worker Exposure Parameters. The exposure parameters for the construction worker are shown in Table 3-4.2 (surface soil, future land use), Table 3-4.3 (subsurface soil, future land use), Table 3-4.4 (soil/outdoor trench air, future land use), Table 3-4.5 (shallow groundwater, future land use), and Table 3-4.6 (shallow groundwater/outdoor trench air, future land use). These exposure parameters rely partially on default CTE and RME exposure parameters presented in the *Exposure Factors Handbook* (EPA, 1997a), the *Supplemental Soil Screening Guidance* (EPA, 2002c) and *RAGS, Part E Supplemental Guidance for Dermal Risk Assessment* (EPA, 2004b).

Construction workers are expected to experience direct exposure to surface soil, subsurface soil, and shallow groundwater via incidental ingestion and direct dermal contact at each of the properties. Inhalation of fugitive dusts from surface and subsurface soil may also occur. Construction workers may also be exposed to contaminated outdoor air in the breathing zone during excavation and trenching attributable to volatile contaminants in surface soil, subsurface soil, and groundwater.

For the soil ingestion pathway, the default contact intensive soil ingestion rate of 330 mg/day (EPA, 2002c) was used for both RME and CTE cases to provide a conservative evaluation of exposure. For groundwater, an ingestion rate 0.05 liters/day of groundwater was assumed for both the RME and CTE cases based on professional judgment. This value represents the ingestion of approximately one mouthful of water per day. For both soil and groundwater, it was assumed that construction workers may be exposed for 125 days/year (5 days per week for a 6-month construction project) for the RME scenario and 40 days/year (5 days per week for an 8-week construction project) for the CTE scenario. The fraction of soil ingested from the Site was assumed to be 100% for both the CTE and RME cases.

The exposure duration of 1 year was assumed for both the RME and CTE cases. The default value of 70 kg for an adult body weight was used for both RME and CTE cases (EPA, 2002c). As recommended in *RAGS* (EPA, 1989), the averaging time for non-carcinogens was set equal to the exposure duration, and the averaging time for carcinogens was the standard EPA lifetime duration (70 years).

For the dermal pathway, skin surface areas were calculated for the body parts that could contact soil or groundwater using statistical distributions of surface areas provided in *RAGS, Part E Supplemental Guidance for Dermal Risk Assessment* (EPA, 2004b). Construction workers were assumed to contact soil and/or groundwater with 3,300 cm^2 of body surface area for both the RME and CTE cases (50^{th} percentile value; EPA, 2004b). The surface area assumes exposure to the face, forearms, hands and lower legs. A soil-to-skin adherence factor of 0.3 mg/cm^2-day was used for both the CTE and RME cases (50^{th} percentile value for utility workers; EPA, 2002c), an activity selected to represent a reasonable high-end activity for this receptor.

Dermal absorption factors provided in Exhibit 3-4 of *RAGS, Part E Supplemental Guidance for Dermal Risk Assessment* (EPA, 2004b) were used to evaluate risk associated with dermal contact with soil. In the absence of recommended dermal absorption factors, dermal exposure to the remaining soil COPCs was not assessed as recommended by EPA (EPA, 2004b).

For the inhalation pathway, construction workers were assumed to engage in activities resulting in the inhalation of fugitive dusts and volatile compounds from the subsurface for 8 hours/day. Air EPCs were modeled from soil and groundwater COPC concentrations as described in subsection 3.2.2.5. Exposure frequencies were the same as those selected for ingestion/dermal contact related exposures. The remaining exposure parameters for the inhalation pathway (i.e., exposure duration and averaging time) were the same values described for the soil ingestion pathway

3.4 Toxicity Assessment

The toxicity assessment identifies the potential effects that are associated with exposure to a COPC. The toxicity assessment considers chronic (long-term) exposures. Two types of toxic effects are evaluated in a risk assessment: carcinogenic effects and non-carcinogenic effects. Noncarcinogenic health effects refer to toxicological effects other than cancer such as toxicity to the liver, kidneys or central nervous system. Carcinogenic health effects refer to the increased cancer risk from exposure to a substance.

Because toxic effects can differ by route of exposure (e.g., oral or inhalation), dose-response values for the oral and inhalation routes of exposure were used in this evaluation. To quantify non-carcinogenic effects, oral and inhalation toxicity values were used. Oral reference doses (RfDs) in units of mg/kg-day and inhalation reference concentrations (RfCs) in units of mg/m^3 that are "estimates (with uncertainty spanning perhaps an order of magnitude) of a daily exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime" (EPA, 1989). In the absence of dermal toxicity factors, EPA uses an oral-to-dermal extrapolation as describes in RAGS E (EPA, 2004b). Table 3-5.1 presents non-cancer toxicity data for the oral and dermal pathways; Table 3-5.2 presents the non-cancer toxicity data for the inhalation pathway. Appendix D, Table 5, presents the non-cancer toxicity data for the COPCs selected for the vapor intrusion indoor air pathway at the existing Aberjona residence.

Oral cancer slope factors (CSFs) in units of $(mg/kg\text{-}day)^{-1}$ and inhalation unit risk (IUR) factors in units of $(ug/m^3)^{-1}$ were used to assess potential cancer effects. The cancer slope factor, or CSF, is a plausible upper bound estimate of carcinogenic potency used to calculate cancer risk from exposure to carcinogens, by relating estimates of lifetime average chemical intake to the incremental probability of an individual developing cancer over a lifetime. The IURs are the upper-bound excess lifetime cancer risks estimated to result from continuous exposure to an agent at a concentration of 1 µg/m³ in air. The CSFs and IURs developed by the EPA are plausible upper bound estimates, which means that EPA is reasonably confident that the actual cancer risk will not exceed the estimated risk calculated using these toxicity values.

The weight-of-evidence classifications, which characterize the extent to which the available data support the hypothesis that an agent causes cancer in humans, are presented for carcinogenic COPCs for the oral/dermal and inhalation pathways, along with the CSFs and IURs in Table 3-6.1 and Table 3-6.2, respectively. Appendix D, Table 6, presents the IURs used for the COPCs for the vapor intrusion indoor air pathway at the existing Aberjona residence.

Toxicity data used in this assessment are from the EPA Integrated Risk Information System (IRIS) on-line database (EPA, 2014), the EPA Superfund Technical Support Center (STSC), the California Environmental Protection Agency (CalEPA), the Agency for Toxic Substances and Disease Registry (ATSDR) and the New Jersey Department of Environmental Protection (NJDEP). The selection of toxicity values was based on the EPA (2003b) recommended hierarchy for human health toxicity values. The EPA (2003b) memorandum on human health toxicity values describes a three-tiered hierarchy that consists of: Tier 1 – Integrated Risk Information System (IRIS); Tier 2 – Provisional Peer Reviewed Toxicity Values developed by STSC; and Tier 3 – Other Toxicity Values, including EPA and non-EPA sources, such as CalEPA, ATSDR, NJDEP and the Health Effects Assessment Summary Tables. A CSF available from CalEPA was used as a Tier 3 value to quantify potential cancer risks associated with exposure to dioxin-like PCBs. The potential cancer risks associated with exposure to dioxin-like PCBs using a cancer slope factor published by EPA in 1985 (EPA, 1985) is discussed in the uncertainty section.

3.4.1 Toxicity Information for Noncarcinogenic Effects

Systemic toxic effects other than cancer can be associated with exposures to chemicals. The reference doses (RfDs) and reference concentrations (RfCs) are the toxicity values that are used to evaluate the potential of developing noncarcinogenic effects as a result of exposure to potentially toxic chemicals. The RfDs and RfCs have been developed on the premise that there are protective mechanisms that must be overcome before an appreciable risk of adverse health effects is manifested during a defined exposure period. It is assumed that there is a threshold dose that must be exceeded before adverse effects can occur.

Chemicals were also evaluated for potential noncarcinogenic toxic effects and were included in the determination of chronic toxicity HQs, which characterize noncancer hazards. Table 3-5.1 summarizes the noncarcinogenic toxicity values (i.e., RfDs) for oral and dermal exposure routes and the corresponding critical effects for the COPCs at the site. Table 3-5.2 summarizes the inhalation noncarcinogenic toxicity values (i.e., RfCs) and the corresponding critical effects for volatile COPCs at the site. Both chronic and, where available, subchronic toxicity values are listed on these tables. When the chronic Reference Dose (RfD) or chronic Reference Concentration (RfC) is based on a subchronic study, a subchronic RfD has been developed by the elimination of the 10-fold uncertainty factor. Chronic RfCs for the vapor intrusion indoor air pathway at the existing Aberjona residence are provided in Appendix D, Table 5.

For mercury, the RfD for inorganic mercury was used to evaluate soil exposures. However, since mercury in sediments may exist as organic mercury compounds, the RfD for organic mercury was used to evaluate sediment exposures.

Due to a lack of reliable chromium speciation data for surface water, all chromium in this medium was evaluated using the hexavalent chromium RfD. For soil, sediment and groundwater, total chromium was evaluated using the trivalent chromium RfD, except in cases where hexavalent chromium was detected or extrapolated to be present based on an assumed percentage of the total chromium concentration existing in the hexavalent form (see subsection 3.2.2.7 for additional information). In these cases, the hexavalent chromium RfD was used.

The certain constituents lacking compound-specific screening criteria (e.g., 2-methylnaphthalene), a surrogate compound was selected (e.g., naphthalene). Specific instances where surrogate assignments were made are identified in footnotes on Tables 3-5.1, 3-5.2, 3-6.1 and 3-6.2.

Chemical-specific permeability coefficients (K_ps), used to evaluate the groundwater and surface water dermal pathways, are provided in Appendix B.4.

3.4.2 Toxicity Information for Carcinogenic Effects

The potential for human carcinogenic effects is evaluated based on the chemical-specific oral cancer slope factors (CSFs) and inhalation Unit Risk (IUR) values along with the weight-of-evidence classification of the EPA. The CSF and IUR values are the toxicity values that quantitatively define the dose-response relationship of a known or suspected carcinogen. The CSF and IUR are estimates of an upper-bound lifetime probability of an individual developing cancer following exposure to a potential cancer-causing agent over his or her lifetime. The CSFs and IURs for chemicals are generally expressed as the 95-percent UCL of the slope of the dose-response curve and are derived by assuming low-dose linearity and applying a computer model to extrapolate from the relatively high doses administered to animals (or the exposures observed in epidemiological studies) to the lower environmental exposure levels that generally occur in humans. The EPA has developed CSFs and IURs for chemicals classified as carcinogens, based on the premise that there is no threshold, i.e., there is no level of exposure below which there is no risk of a carcinogenic effect.

Because the CSF and IUR are generally the 95-percent UCL of the probability of a response per unit intake of a chemical over a lifetime exposure, the use of such CSFs and IURs is expected to result in a conservative (i.e., upper-bound) estimate of potential cancer risk.

Table 3-6.1 summarizes the oral and dermal carcinogenic toxicity values (i.e., CSFs) and the corresponding weight-of-evidence classifications. Table 3-6.2 summarizes the inhalation carcinogenic toxicity values (IURs). For PAHs, the SF for B(a)P, along with the appropriate

relative potency factors (EPA, 1993), have been used to evaluate the potency of the individual carcinogenic PAHs. IURs for the vapor intrusion indoor air pathway at the existing Aberjona residence are provided in Appendix D, Table 6.

Prior to carcinogenic evaluation, the detected concentrations of dioxin-like PCBs were adjusted to Toxicity Equivalence (TEQ) concentrations using methodology and Toxic Equivalence Factors (TEFs) recommended by EPA (2010). The concept of TEFs has been developed and introduced to facilitate risk assessment and regulatory control of exposure to complex environmental mixtures of classes of compounds. TEFs are used to represent the toxicity of isomers, congeners and homologues of dioxin-like PCBs relative to 2,3,7,8-tetrachlorodibenzo-p-dioxin (2,3,7,8-TCDD), which is assigned a TEF of unity. For example, an isomer assigned a TEF of 0.1 indicates that the isomer is approximate 10-fold less potent than 2,3,7,8-TCDD. The environmental concentrations of the isomers and congeners are multiplied by their respective TEFs and then summed together to derive an adjusted environmental concentration (the TEQ) that factors in the relative toxicity of the compounds. The TEQ is then used, along with the slope factor for 2,3,7,8-TCDD, to estimate cancer risk for dioxin-like PCBs as a group.

The quantitative evaluation of potential risks for carcinogens with a mutagenic mode of action (i.e., vinyl chloride, methylene chloride, carcinogenic PAHs, chromium VI and TCE-induced kidney tumors) followed EPA guidance entitled *Supplemental Guidance for Assessing Susceptibility from Early-Life Exposure to Carcinogens* (EPA, 2005b). Specifically, the quantification of cancer risks for child receptor involves the use of age-dependent adjustment factors (ADAFs). An ADAF of 10 was used for childhood exposures occurring from birth to 2 years of age, and an ADAF of 3 was used for exposures occurring between the ages of 2 and 16 (EPA, 2005). An ADAF of 1 was used for adult exposures. For vinyl chloride, the compound-specific methodology recommended in EPA's *Toxicological Review for Vinyl Chloride* was used (EPA, 2014). This methodology is further discussed in Section 3.5.1.

3.4.3 Adjustment of Toxicity Factors

No RfDs or CSFs specific to dermal exposure are available. Therefore, cancer risks and HIs associated with dermal exposure may be evaluated using an oral CSF or RfD, adjusted such that the toxicity value is appropriate for the dermal pathway. As detailed by EPA, for purposes of evaluating dermal exposure, it is generally necessary to adjust an oral toxicity factor (i.e., RfD or CSF) from an administered (i.e., applied) dose to an absorbed (i.e., internal) dose (EPA, 1989). Because the toxicity values for the COPCs at the study area are expressed as orally administered doses (i.e., applied or intake-based), it is necessary to adjust both the RfDs and CSFs for these substances in estimating exposure on an absorbed-dose basis when assessing dermal exposure.

The oral RfDs and oral CSFs for each COPC were modified according to the following equations for use in assessing dermal exposure (EPA, 1989):

$$ERfD_o = RfD_o \times BF_{o,a}$$

$$ECSF_o = CSF_o / BF_{o,a}$$

where:

- $ERfD_o$ = effective absorbed-dose oral RfD for each chemical (i.e., adjusted dermal RfD)
- RfD_o = oral RfD for each chemical
- $BF_{o,a}$ = absolute oral bioavailability factor for each chemical (i.e., oral to dermal adjustment factor)
- $ECSF_o$ = effective absorbed-dose oral CSF for chemical (i.e., adjusted dermal CSF)
- CSF_o = oral CSF for each chemical

Tables 3-5.1 and 3-6.1 present the oral to dermal adjustment factors used to adjust the oral toxicity criteria for the COPCs evaluated in the dermal exposure pathways. Oral bioavailability values were derived from data presented in RAGS, Part E (EPA, 2004b). No adjustment for oral absorption efficiency has been applied to any COPC with an absorption efficiency of greater than 50%.

3.4.4 Toxicity Information for Arsenic in Sediment

To more accurately assess the oral toxicity of arsenic in sediments at the site, the site-specific oral bioavailability study conducted for the Aberjona River Study Baseline Risk Assessment (EPA, 2004a and 2005a) was utilized. This study was initiated for the Aberjona River Study because oral bioavailability studies at other sites have indicated that the actual oral bioavailability of arsenic from some soils is significantly less than 100%.

The report entitled *Relative Bioavailability of Arsenic in Sediments from the Aberjona River* (Castell et al., 2002), details the methods and results of the study conducted for the Aberjona River Study Area and is included in its entirety in Aberjona River Study Baseline Risk Assessment (EPA, 2004a and 2005a). In this study, young swine were fed sediments from the Aberjona River study area that contained arsenic at various known levels. Data were collected to calculate the relative bioavailability (RBA) of arsenic from these sediments. RBA is an estimate of the oral bioavailability of arsenic from study area sediments compared to that of a reference arsenic compound administered in drinking water. "Best Estimate" RBA values determined in this study ranged from 37 to 51%, indicating that arsenic from sediments is absorbed less extensively than arsenic from drinking water. These site-specific RBA estimates are also less than the default value of 100% for oral absorption efficiency of arsenic. The most conservative RBA value determined for study area sediments (51%) was selected as the most appropriate to evaluate the oral toxicity of arsenic in sediments at the Murphy Wetland.

The site-specific RBA value of 51% was used to adjust the oral RFD and CSF for arsenic to derive a site-specific estimate of oral toxicity of arsenic in sediments. The oral RfD and oral CSF for arsenic were modified according to the following equations from Castell et al. (2002) for use in assessing oral sediment exposures for arsenic:

$$RfD_{adjusted} = RfD_{IRIS} / RBA$$

$$CSF_{adjusted} = CSF_{IRIS} \times RBA$$

where:

$RfD_{adjusted}$	=	adjusted oral RfD for arsenic in sediment
RfD_{IRIA}	=	oral RfD for arsenic as listed in IRIS (EPA, 2014)
RBA	=	site-specific relative bioavailability factor for arsenic (i.e., 0.51)
$CSF_{adjusted}$	=	adjusted oral CSF for arsenic in sediment
CSF_{IRIS}	=	oral CSF for arsenic as listed in IRIS (EPA, 2014)

Tables 3-5.3 and 3-6.3 present the adjusted oral RfD and adjusted oral CSF for arsenic, respectively. These adjusted toxicity values were used to evaluate ingestion exposures to arsenic in sediment only. Arsenic toxicity values were not changed for the evaluation of arsenic in other media or by the dermal route of exposure.

3.4.5 Toxicity of Lead

Lead was selected as a COPC in soil, groundwater and sediment. Lead in soil and sediment exceeded the residential soil screening value of 400 mg/kg (EPA, 1994a). No RfD or CSF is available for lead. Therefore, EPA has recommended some alternative approaches to evaluate lead exposures. For soil and sediment, childhood lead exposures were evaluated through the use of the Integrated Exposure Uptake Biokinetic (IEUBK) Model (EPA, 1994b, 2007). Appendix B.6 (Lead Model Calculations) contains summary information showing the IEUBK model inputs. This model uses algorithms to calculate a soil lead concentration protective of a childhood blood lead level of 10 micrograms per deciliter (µg/dL). The average weekly time-weighted soil or sediment lead concentration was used as the soil or sediment concentration in the model (EPA, 2003c). Default values, as recommended in the model, were used for all other inputs (see Appendix B.6).

Lead exposures were evaluated for the adult worker, adult recreational user, adult construction worker, and older child trespasser through the use of methodology provided in Recommendations of the Technical Workgroup for Lead for an Approach to Assessing Risk Associated with Adult Exposures to Lead in Soil and updates (EPA, 2003a; 2009a). This

methodology uses algorithms to relate soil lead intake to blood lead concentrations in women of childbearing age. The model calculates a soil lead concentration protective of a site-specific maternal blood lead level that will be protective of a 95th percentile fetal blood level of 10 μg/dL. The average weekly time-weighted soil or sediment lead concentration was used as the soil or sediment concentration in the model (EPA, 2003c). Appendix B.6 document the calculation of a site-specific maternal blood lead level for each scenario using a geometric standard deviation (GSD) in intake and biokinetics of 1.8, which is typical of populations in small areas dominated by a single source of lead exposure. A typical blood lead concentration in women of child-bearing age in the absence of study area exposures was assumed to be 1.0 μg/dL (EPA, 2009a). All other model inputs are presented on tables in Appendix B.6.

The exposure frequency was based on the RME scenario being evaluated (e.g., 2 to 5 days per week depending on the receptor). For the adult commercial worker, adult recreational user and older child trespasser, the ingestion rate was assumed to be 100 mg/day and for the construction worker, 330 mg/day. The time-weighted average soil or sediment lead concentration was used as the soil or sediment concentration in the model (EPA, 2003c). The calculation of the time-weighted average lead concentrations in soil and sediment is presented in Appendix B.6.

3.5 Risk Characterization

Risk characterization combines estimates of exposure with toxicity data to develop estimates of non-cancer health hazards and cancer risks. The risk characterization was divided into three phases: 1) risk estimation; 2) risk description; and 3) uncertainty analysis.

Risk estimation is undertaken by combining the toxicity factors and exposure assessment equations to calculate estimates of cancer risks and non-cancer hazard indices (HIs). Noncarcinogenic risks are reported as pathway-specific HIs, which are the sum of individual COPC HQs for that exposure pathway. Only HQs from COPCs that affect the same target organ are summed to generate HIs. Estimates of carcinogenic risks are reported as incremental (above background cancer risk experienced by all individuals in daily life) lifetime cancer risks (ILCRs). Current practice considers carcinogenic risks to be additive when assessing exposure

to a mixture of hazardous substances. Risk description entails several discussions, including the relative contributions of individual exposure pathways to the total risk for each medium. The significance of the risk estimates are relative to risk management criteria set forth in EPA policy. The uncertainty analysis describes and quantifies, where possible, the impact of data uncertainty and variability, exposure assumptions, and toxicity values on estimates of risk.

3.5.1 Risk Estimation

Noncancer risk is estimated by means of a HQ. To calculate noncarcinogenic HQs, the ADDs, calculated as described in subsection 3.3.2, were divided by the RfDs as follows:

$$HQ = ADD / RfD$$

The sum of this ratio for all chemicals within a property/area and pathway that have the same target organ or type of toxicity is termed the pathway HI. The HI is useful as a reference point for gauging potential effects of environmental exposures to complex mixtures. In general, HIs that are less than 1 are not of regulatory concern; however, a HI of greater than 1 does not automatically indicate that an adverse effect will occur and should not automatically be interpreted as posing an unacceptable risk to the exposed population.

The total pathway HI for each property/area was calculated by summing the HQs for the COPCs having similar systemic effects. Total HIs for each receptor, by medium, were calculated by summing the total pathway HIs across pathways within media (e.g., summing dermal and ingestion sediment risks). As a first approximation, all COPCs are assumed to have additive effects. Total pathway HIs, assuming additivity of effects, are presented on Tables 3-7.1 through 3-7.9. HIs for the vapor intrusion indoor air inhalation pathway at the existing Aberjona residence are presented in Appendix D, Tables 7.1 through 7.4. However, in cases where the total pathway HI for a receptor exceeded 1, only COPCs having similar systemic effects (i.e., target organs) were summed for each pathway and medium. Target organ HIs are presented on Tables 3-9.1 through 3-9.26, and in Appendix D, Tables 9.1 and 9.2, for the vapor intrusion indoor air pathway at the existing Aberjona residence.

The cancer risk of each receptor is estimated for each medium by means of an ILCR. EPA (1991b) states that where the cumulative incremental current or future carcinogenic risk to a receptor is less than 10^{-4}, and where the noncarcinogenic HI is less than 1, action generally is not warranted unless there are adverse environmental impacts (EPA, 1991b).

To calculate ILCR, the chemical- and pathway-specific LADDs, calculated as described in subsection 3.3.2, were multiplied by CSFs as follows:

$$ILCR = CSF \times LADD$$

The resulting value represents the upper-bound probability that an individual could develop cancer over his or her lifetime due to exposure to potential carcinogens under the conditions specified in the exposure scenario. For example, carcinogenic risk levels of 10^{-6} and 10^{-4} represent a one-in-one-million chance and a one-in-ten-thousand chance, respectively, that an individual could develop cancer over a lifetime.

The cancer risk for each pathway (e.g., the sediment ingestion pathway) was calculated by summing the risks from each COPC at each property/area within the pathway, while receptor risks for each medium were calculated by summing ILCRs for each pathway within the medium (e.g., the sediment ingestion and dermal contact pathways). Receptor cancer risk from exposure to soil, groundwater, outdoor trench air, surface water and sediment within a property/area was determined by adding the risk from each medium and pathway, as appropriate. ILCRs were further summed for child and adult receptors to derive a total receptor cancer risk for the recreational and residential receptors. The total receptor ILCRs are presented on Tables 3-9.1 through 3-9.26, and in Appendix D, Tables 9.1 and 9.2, for the vapor intrusion indoor air pathway at the existing Aberjona residence.

Total receptor cancer risk from each medium is presented by property/area. Risk was not summed across the properties since the parameter values used assume maximal exposure within

each exposure area. This approach assumes that an individual would not be maximally exposed to media at more than one property.

Vinyl chloride, trichloroethene, methylene chloride, carcinogenic PAHs and chromium VI were selected as COPC in one or more medium. Each of these chemicals has been determined by EPA to produce tumors through a mutagenic mode of action. The quantification of potential cancer risks for carcinogens with a mutagenic mode of action followed the EPA guidance entitled *Supplemental Guidance for Assessing Susceptibility from Early-Life Exposure to Carcinogens* (EPA, 2005b).

For chemicals that initiate carcinogenesis by a mutagenic mode of action and for which data concerning differential susceptibility for early life stages is available, EPA may develop SFs and UR values that are applicable to specific ages (e.g., infants). This approach has been used by EPA to develop SFs and UR values for vinyl chloride. The recommended approach for vinyl chloride (EPA, 2014) has been used to quantify the early-life cancer risk associated with the young child drinking water and incidental ingestion sediment and soil pathways.

The quantification of cancer risks for older child trespassers, recreational users and residents involves the use of ADAFs for each of the remaining chemicals identified as COPCs with mutagenic modes of action (trichloroethene, methylene chloride, carcinogenic PAHs and chromium VI). Specifically, an ADAF of 10 was used for exposures occurring to children from birth to 2 years of age and an ADAF of 3 was used for exposures occurring between the ages of 2 and 16. The following general equation demonstrates how ADAFs were incorporated into the oral/dermal and inhalation risk calculations:

$$\textbf{Risk}_{\textbf{oral/dermal}} = \textbf{Exposure dose (mg/kg-day) x CSF (mg/kg-day)}^{-1} \textbf{ x ADAF}$$

$$\textbf{Risk}_{\textbf{inhalation}} = \textbf{Exposure concentration (ug/m}^3\textbf{) x IUR (ug/m}^3\textbf{)}^{-1} \textbf{ x ADAF}$$

For trichloroethene, ADAFs are only applicable to the slope factor and unit risk for kidney tumors associated with trichloroethene exposure (9.3×10^{-3} $(mg/kg\text{-}day)^{-1}$ and 1×10^{-6} $[ug/m^3]^{-1}$). ADAFs were not applied to the slope factor and unit risk associated with trichloroethene-induced

liver tumors and non-Hodgkins lymphoma (3.7×10^{-2} $(mg/kg\text{-}day)^{-1}$ and 3.1×10^{-6} $[ug/m^3]^{-1}$) since these types of cancers were not associated with a mutagenic mode of action.

The older child was included with the 24-year adult exposure in order to include the ADAF of 3 applicable to ages 6 through 16.

The specific formulas used for the ADAF calculations are provided in footnotes at the bottom of Tables 3-7.1 through 3-7.9 and Appendix D, Tables 7.1 through 7.4. The total receptor ILCRs are presented on Tables 9.1 through 9.26 and Appendix D, Tables 9.1 and 9.2.

3.5.2 Risk Description

This subsection summarizes the human health risks potentially associated with exposures to environmental media (surface/subsurface soil, groundwater, outdoor trench air, indoor air, surface water and sediment). Individual chemical-specific carcinogenic risks are expressed as probabilities of developing cancer (i.e., ILCRs), while noncarcinogenic risks are expressed as HIs. All carcinogenic and noncarcinogenic risks were calculated using both CTE and RME methods. The RME represents the reasonable maximum exposure and risk a receptor may receive from a property/area. The CTE represents the average exposure and risk at a property/area.

The risk description for the Southwest Properties is provided below in two parts. First, the relative contributions of the various exposure pathways within each medium are analyzed for each receptor. Second, the relative contributions of each contaminant are analyzed for each receptor.

Tables 3-9.1 through 3-9.26 and Appendix D, Tables 9.1 and 9.2, present target-organ specific HIs, which are discussed if a medium-specific HI exceeds 1. For the recreational and residential receptors, child and adult ILCRs have been summed to present the total receptor cancer risk. However, because the child receptor is the most sensitive receptor for the estimation of

noncarcinogenic risks, only the child receptor HIs have been presented on these tables for these receptors.

3.5.2.1 Description of HI Estimates

HI estimates represent the risk of health effects other than cancer from exposure to contaminants within the Southwest Properties, as described in subsection 3.5.1. Tables 3-7.1 through 3-7.9 and Appendix D, Tables 7.1 through 7.4, present the non-carcinogenic risks by receptor and medium for each of the three properties, the Murphy Wetland and the future resident. When a receptor-specific HI for an exposure medium exceeded 1, HIs were segregated by target organ and discussed as to whether target organ-specific HIs exceed the risk management criterion. These target organ HIs are presented on Tables 3-9.1 through 3-9.26 and in Appendix D, Tables 9.1 and 9.2.

The following summarizes the estimated HIs for the evaluated pathways and media for each of the three properties, the Murphy Wetland, the existing Aberjona residence and the future resident exposed to contaminants in tap water. HQs for contaminants that contributed significantly to HIs in excess of the risk management criterion are noted, where appropriate. The existing Aberjona residence is considered a separate exposure point for the vapor intrusion pathway. The Murphy Wetland is also evaluated as a separate exposure point for the current/future trespasser and future recreational user. The additive effect of exposure to the Murphy Wetland and soil at the Murphy and Whitney properties is evaluated qualitatively where appropriate.

Aberjona Property

Adult Commercial Worker. The estimated HIs for the adult commercial receptor at the Aberjona property are presented in Tables 3-7.1 and 3-7.2 for current and future land use, respectively. The cumulative risks for the media evaluated are presented in Tables 3-9.1 and 3-9.8 for current and future land use, respectively. Current and future HIs are calculated assuming incidental ingestion of and dermal contact with surface soil. The RME and CTE HIs are below the target HI of 1. The future vapor intrusion pathway will require further evaluation if a change

in usage of the existing commercial building is contemplated that would result in higher occupancy (e.g., daycare use of the building), or as part of new building construction including any addition to the existing building. Use of a vapor barrier or subslab system may be appropriate to mitigate the vapor intrusion pathway in instances of future development/construction of occupied buildings.

Older Child Trespasser. The estimated HIs for the older child trespasser at the Aberjona property are provided in Table 3-7.4 for future land use. The cumulative risks for the media evaluated are presented in Table 3-9.7. HIs are calculated assuming incidental ingestion of and dermal contact with surface soil. The RME and CTE HIs are below the target HI of 1.

Adult Recreational User. The future recreational user was evaluated for exposures to surface soil and subsurface soil. Surface soil exposures assume that the soils are not disturbed in the future. Subsurface soil exposures assume that future site use results in the relocation of subsurface soil to the surface.

The estimated HIs for the future adult recreational user exposed to media including surface soil and subsurface soil at the Aberjona property are provided in Table 3-7.7. For this scenario, HIs are calculated assuming incidental ingestion of and dermal contact with surface soil or subsurface soil. The RME and CTE HIs are below the target HI of 1.

Young Child Recreational User. The future recreational user was evaluated for exposures to surface soil and subsurface soil. Surface soil exposures assume that the soils are not disturbed in the future. Subsurface soil exposures assume that future site use results in the relocation of subsurface soil to the surface.

The estimated HIs for the future young child recreational user exposed to media including surface soil and subsurface soil at the Aberjona property are provided in Table 3-7.8. For this scenario, HIs are calculated assuming incidental ingestion of and dermal contact with surface soil and subsurface soil. The cumulative risks for the media evaluated are presented in Table 3-9.8,

for surface soil. Table 3-9.9 presents the cumulative risks including subsurface soil. The RME and CTE HIs are below the target HI of 1.

Construction Worker. The future construction worker was evaluated for exposures to surface soil and subsurface soil. Subsurface soil risk was evaluated in combination with incidental ingestion of and dermal contact with shallow groundwater.

The estimated HIs for the future construction worker exposed to surface soil at the Aberjona property are provided in Table 3-7.9. For this scenario, HIs are calculated assuming incidental ingestion of and dermal contact with surface soil and inhalation of particulates from surface soil. The RME and CTE cumulative risks for the media evaluated are presented in Table 3-9.10. The cumulative HIs are below the target HI of 1.

The estimated HIs for the future construction worker exposed to subsurface soil and shallow groundwater at the Aberjona property are provided in Table 3-7.9. For this scenario, HIs are calculated assuming incidental ingestion of and dermal contact with subsurface soil; inhalation of particulates from subsurface soil; and incidental ingestion of and dermal contact with shallow groundwater. The RME and CTE cumulative risks for the media evaluated are presented in Table 3-9.11. The cumulative HIs are below the target HI of 1.

Existing Aberjona Residence. The estimated HIs for the current and future young child and adult resident exposed to vapor intrusion pathway VOCs in indoor air at the existing Aberjona residence are provided in Appendix D, Tables 7.1 through 7.4. For this scenario, HIs are calculated assuming inhalation of indoor air VOCs only. The cumulative risks for adults and children combined are presented in Appendix D, Tables 9.1 and 9.2. The RME and CTE HIs are below the target HI of 1. Naphthalene and TCE are the primary contributors to the HIs.

Though naphthalene was detected in shallow groundwater upgradient of the existing Aberjona residence, it was only detected in one of eight monitoring wells (AB-201) at a relatively low concentration in groundwater (9.49 µg/L). This monitoring well is located approximately 200 feet from the existing Aberjona residence. In addition, naphthalene was only detected once at a

low estimated concentration in the soil gas beneath the building (0.21 J ug/m^3). Therefore, naphthalene is likely present in indoor air due to an indoor source. Though TCE, PCE and chloroform were not found at significant concentrations for resident exposure in any indoor air samples, subslab soil gas concentrations of these compounds are greater than EPA soil gas screening levels (EPA, 2013a) for residential properties, with the subslab soil gas concentrations of TCE being the most elevated. The presence of elevated concentrations of VOCs, in particular TCE, in subslab soil gas beneath the existing Aberjona residence indicates a potential for future vapor intrusion to occur if building conditions were to change.

Whitney Property[6]

Adult Commercial Worker. The estimated HIs for the adult commercial receptor at the Whitney property are provided in Tables 3-7.1 and 3-7.2 for current and future land use, respectively. Current and future HIs are calculated assuming incidental ingestion of and dermal contact with surface soil. The RME and CTE cumulative risks for the media evaluated are presented in Tables 3-9.2 and 3-9.12 for current and future land use, respectively. The cumulative HIs are below the target HI of 1. The future vapor intrusion pathway will require further evaluation if a change in usage of the existing commercial building is contemplated that would result in higher occupancy (e.g., full-time commercial use of the building), or as part of new building construction including any addition to the existing building. Use of a vapor barrier or subslab system may be appropriate to mitigate the vapor intrusion pathway in instances of future development/construction of occupied buildings.

Older Child Trespasser. The estimated HIs for the older child trespasser at the Whitney property are provided in Tables 3-7.3 and 3-7.4 for current and future land use, respectively. The

[6] Worker protective measures should be used if excavation work is performed prior to remedy implementation near the rear of the building in the vicinity of the drain line connecting the former Whitney drum storage area to the municipal sewer system. During test pit excavtion activities in this area in 2011, odors were observed and workers were outfitted with half-faced respirators with organic vapor cartridges due to elevated VOC readings.

current and future HIs are calculated assuming incidental ingestion of and dermal contact with surface soil. The cumulative risks for the media evaluated are presented in Tables 3-9.3 and 3-9.13 for current and future land use, respectively. The cumulative HIs are below the target HI of 1.

Adult Recreational User. The future recreational user was evaluated for exposures to surface soil and subsurface soil. Surface soil exposures assume that the soils are not disturbed in the future. Subsurface soil exposures assume that future site use results in the relocation of subsurface soil to the surface.

The estimated HIs for the future adult recreational user exposed to surface soil at the Whitney property are provided in Table 3-7.7. HIs are calculated assuming incidental ingestion of and dermal contact with surface soil. The RME and CTE HIs are below the target HI of 1.

The estimated HIs for the future adult recreational user exposed to subsurface soil at the Whitney property are provided in Table 3-7.7. HIs are calculated assuming incidental ingestion of and dermal contact with subsurface soil. The RME and CT HIs of 10 and 3 respectively, exceed the target HI of 1 due to direct contact with subsurface soil. Major contributors to the RME risk include total PCBs and PCB TEQ. The major contributor for the CTE risk is total PCBs.

Young Child Recreational User. The future recreational user was evaluated for exposures to surface soil and subsurface soil. Surface soil exposures assume that the soils are not disturbed in the future. Subsurface soil exposures assume that future site use results in the relocation of subsurface soil to the surface.

The estimated HIs for the future young child recreational user exposed to surface soil at the Whitney property are provided in Table 3-7.8. HIs are calculated assuming incidental ingestion of and dermal contact with surface soil. The RME and CTE cumulative risks for the media evaluated are presented in 3-9.14. The CTE HI is below the target HI of 1. The RME HI of 3 exceeds the target HI of 1 due to direct contact with surface soil. The major contributor to the RME risk is total PCBs.

The estimated HIs for the future young child recreational user exposed to subsurface soil at the Whitney property are provided in Table 3-7.8. HIs are calculated assuming incidental ingestion of and dermal contact with subsurface soil. The RME and CTE cumulative risks for the media evaluated are presented in 3-9.15. The RME and CTE HIs of 100 and 20, respectively, exceed the target HI of 1 due to direct contact with subsurface soil. Major contributors to the RME and CTE risk include total PCBs and PCB TEQ.

Construction Worker. The future construction worker was evaluated for exposures to surface soil and subsurface soil. Subsurface soil risk was evaluated in combination with inhalation of outdoor trench air attributable to contaminated subsurface soil and groundwater, as well as incidental ingestion of and dermal contact with shallow groundwater.

The estimated HIs for the future construction worker exposed to surface soil at the Whitney property are provided in Table 3-7.9. HIs are calculated assuming incidental ingestion of and dermal contact with surface soil; and inhalation of particulates associated with surface soil. The RME and CTE cumulative risks for the media evaluated are presented in Table 3-9.16. The RME and CTE HIs are below the target HI of 1.

The estimated HIs for the future construction worker exposed to media including subsurface soil are provided in Table 3-7.9. HIs are calculated assuming incidental ingestion of and dermal contact with subsurface soil; inhalation of particulates associated with subsurface soil; incidental ingestion of and dermal contact with shallow groundwater; and inhalation of outdoor trench air attributable to contaminants in soil and groundwater. The RME and CTE cumulative risks for the media evaluated are presented in Table 3-9.17. The RME and CTE HIs of 60 and 10, respectively, exceed the target HI of 1. The RME exceedance is due to direct contact with subsurface soil and shallow groundwater; the CTE exceedance is due to direct contact with subsurface soil only. Major contributors to the RME risk include total PCBs and PCB TEQ in subsurface soil and cis-1,2-dichloroethene, tetrachloroethene and trichloroethene in shallow groundwater. Major contributors for the CTE risk include total PCBs and PCB TEQ in subsurface soil.

Murphy Property

Adult Commercial Worker. The estimated HIs for the adult commercial worker are provided in Tables 3-7.1 and 3-7.2, for current and future land use, respectively. The current and future HIs are calculated assuming incidental ingestion of and dermal contact with surface soil. The RME and CT cumulative risks for the media evaluated are presented in Tables 3-9.4 and 3-9.18 for current and future land use, respectively. The estimated RME and CTE HIs are below the target HI of 1. The future vapor intrusion pathway will require further evaluation if a change in usage of the existing commercial building is contemplated that would result in higher occupancy (e.g., full-time commercial use of the building), or as part of new building construction including any addition to the existing building. Use of a vapor barrier or subslab system may be appropriate to mitigate the vapor intrusion pathway in instances of future development/construction of occupied buildings.

Older Child Trespasser. The estimated HIs for the future older child trespasser are provided in Table 3-7.4. The future HIs are calculated assuming incidental ingestion of and dermal contact with surface soil. The RME and CTE cumulative risks for the media evaluated are presented in Table 3-9.19. The estimated RME and CTE HIs are below the target HI of 1.

Adult Recreational User. The future recreational user was evaluated for exposures to surface soil and subsurface soil. Surface soil exposures assume that the soils are not disturbed in the future. Subsurface soil exposures assume that future site use results in the relocation of subsurface soil to the surface.

The estimated HIs for the future adult recreational user exposed to surface soil at the Murphy property are provided in Table 3-7.7. HIs are calculated assuming incidental ingestion of and dermal contact with surface soil. The estimated RME and CTE HIs are below the target HI of 1.

The estimated HIs for the future adult recreational user exposed to media including subsurface soil are provided in Table 3-7.7. HIs are calculated assuming incidental ingestion of and dermal contact with subsurface soil. The estimated RME and CTE HIs are below the target HI of 1.

Young Child Recreational User. The future recreational user was evaluated for exposures to surface soil and subsurface soil. Surface soil exposures assume that the soils are not disturbed in the future. Subsurface soil exposures assume that future site use results in the relocation of subsurface soil to the surface.

The estimated HIs for the future young child recreational user exposed to media including surface soil at the Murphy property are provided in Table 3-7.8. HIs are calculated assuming incidental ingestion of and dermal contact with surface soil. The RME and CTE cumulative risks for the media evaluated are presented in Table 3-9.21. The CTE HI is below the target HI of 1. The RME HI of 3 exceeds the target HI of 1 due to direct contact with surface soil. The major contributor to the RME risk is thallium.

The estimated HIs for the future young child recreational user exposed to subsurface soil are provided in Table 3-7.8. HIs are calculated assuming incidental ingestion of and dermal contact with subsurface soil. The RME and CTE cumulative risks for the media evaluated are presented in Table 3-9.23. The CTE HI is below the target HI of 1. The RME HI of 5 exceeds the target HI of 1 due to direct contact with surface soil. The major contributor to the RME risk is thallium.

Construction Worker. The future construction worker was evaluated for exposures to surface soil and subsurface soil. Subsurface soil risk was evaluated in combination with inhalation of outdoor trench air attributable to contaminated subsurface soil and groundwater, as well as incidental ingestion of and dermal contact with shallow groundwater.

The estimated HIs for the future construction worker exposed to media including surface soil are provided in Table 3-7.9. HIs are calculated assuming incidental ingestion of and dermal contact with surface soil and inhalation of particulates associated with surface soil. The RME and CTE

cumulative risks for the media evaluated are presented in Table 3-9.24. The estimated RME and CTE HIs are below the target HI of 1.

The estimated HIs for the future construction worker exposed to media including subsurface soil are provided in Table 3-7.9. HIs are calculated assuming incidental ingestion of and dermal contact with subsurface soil; inhalation of particulates associated with subsurface soil; incidental ingestion of and dermal contact with shallow groundwater; and inhalation of outdoor trench air attributable to contaminants in subsurface soil and groundwater. The RME and CTE cumulative risks for the media evaluated are presented in Table 3-9.25. The estimated CTE HI is below the target HI of 1. The RME HI of 5 exceed the target HI of 1. The RME exceedance is due to direct contact with shallow groundwater. Major contributor to the RME risk includes cis-1,2-dichloroethene in shallow groundwater.

Murphy Wetland

The Murphy Wetland is evaluated as a separate exposure point for the current and future trespasser and for the future recreational user. Typically, risks associated with surface water and sediment would be evaluated in combination with other Site media. However, due to the location of the Murphy Wetland (i.e., located between the upland portions of the Murphy, Whitney, Wildwood and Aberjona properties), the wetland area is being evaluated as a separate exposure point. Nonetheless, the calculated risk due to surface soil at either of the neighboring properties (Whitney or Murphy property) is significantly less than the risk estimated for sediment.

Older Child Trespasser. The estimated HIs for the older child trespasser are provided in Tables 3-7.3 and 3-7.4 for current and future land use, respectively. HIs are calculated assuming dermal contact with surface water and incidental ingestion of and dermal contact with sediment. The RME and CTE cumulative risks for the media evaluated are presented in Tables 3-9.5 and 3-9.20 for current and future land use, respectively. The current RME HI does not exceed the target HI of 1. However, the future RME HI of 2 exceeds the target HI of 1 due to exposure to sediment.

The major contributor to the future HI is total PCBs. The current and future CTE HIs are less than the target HI of 1.

Adult Recreational User. The estimated HIs for the future adult recreational user are provided in Table 3-7.7. HIs are calculated assuming dermal contact with surface water and incidental ingestion of and dermal contact with sediment. The cumulative RME HI of 2 does not exceed the target HI of 1 when risks were summed only for COPCs with similar target organs. The CTE HI is below the target HI of 1.

Young Child Recreational User. The estimated HIs for the future young child recreational user are provided in Table 3-7.8. HIs are calculated assuming dermal contact with surface water and incidental ingestion of and dermal contact with sediment. The RME and CTE cumulative risks for the media evaluated are presented in Table 3-9.22. The cumulative RME and CTE HIs of 10 and 3, respectively, exceed the target HI of 1 due direct contact with sediment. Major contributors to the RME HI include C11-C22 aromatics and total PCBs. The major contributor for the CTE HI is total PCBs.

Site-Wide Future Resident Tap Water Use

Adult Receptor. The estimated HIs for the future site-wide adult resident are provided in Table 3-7.5. For this scenario, HIs are calculated assuming ingestion of groundwater, dermal contact with groundwater during household water use, and inhalation of volatiles released from water during household water use. The RME and CTE HIs of 2000 and 50, respectively, are above the target HI of 1. The major contributors to the RME HI in excess of 1 are cis-1,2-dichloroethene, trans,1,2-dichloroethene, methylene chloride, tetrachloroethene, 1,2,3-trichlorobenzene, 1,2,4-trichlorobenzene, 1,1,2-trichloroethane, trichloroethene, vinyl chloride, xylenes (total), C5-C8 aliphatics, C9-C12 aliphatics, C9-C18 aliphatics, C11-C22 aromatics, 2-methylnaphthalene, naphthalene, aldrin, PCB TEQ, total PCBs, arsenic, iron, and manganese. The major contributors to the CTE HI in excess of 1 are cis-1,2-dichloroethene, 1,2,4-trichlorobenzene, 1,1,2-trichloroethane, trichloroethene, naphthalene and total PCBs.

Young Child Receptor. The estimated HIs for the future young child resident are provided in Table 3-7.6. For this scenario, HIs are calculated assuming ingestion of groundwater, dermal contact with groundwater during household water use, and inhalation of volatiles released from water during household water use. The RME and CTE cumulative risks for the media evaluated are presented in Table 3-9.26. The RME and CTE HIs of 3000 and 90, respectively, are above the target HI of 1. The major contributors to the RME HI in excess of 1 are benzene, cis-1,2-dichloroethene, trans-1,2-dichloroethene, methylene chloride, tetrachloroethene, 1,2,3-trichlorobenzene, 1,2,4-trichlorobenzene, 1,1,2-trichloroethane, trichloroethene, vinyl chloride, xylenes (total), C5-C8 aliphatics, C9-C12 aliphatics, C9-C10 aromatics, C9-C18 aliphatics, C11-C22 aromatics, 2-methylnaphthalene, naphthalene, PCB TEQ, total PCBs, aldrin, lindane, heptachlor epoxide, arsenic, cobalt, iron, and manganese. The major contributors to the CTE HI in excess of 1 are cis-1,2-dichloroethene, 1,2,4-trichlorobenzene, 1,1,2-trichloroethane, trichloroethene, vinyl chloride, C9-C12 aliphatics, C9-C18 aliphatics, naphthalene, total PCBs, arsenic and manganese.

Though the 2011 and 2013 groundwater sampling data have been used in place of the 2002 sampling data, a similar though somewhat more extensive list of risk-contributing chemicals has been identified using the 2011/2013 data set than was identified in the 2006 baseline risk assessment. The more extensive list of groundwater risk-contributors is due to changes in toxicity values and the more analytically comprehensive data set available for use which reduces the uncertainty associated with the baseline risk assessment.

3.5.2.2 Description of ILCR Estimates

Estimates of ILCR represent the incremental risk of cancer from the Site, as described in subsection 3.5.1. Tables 3-7.1 through 3-7.9 and Appendix D, Tables 7.1 through 7.4, present the cancer risks by receptor and medium. ILCRs were summed for the young child and adult receptors to derive a total receptor risk for the recreational and residential receptors. The total receptor cancer risks, summed for the adult and child receptors where appropriate, are presented on Tables 3-9.1 through 3-9.26 and Appendix D, Tables 9.1 and 9.2.

Aberjona Property

Adult Commercial Worker. The estimated RME and CT ILCRs for the adult commercial worker at the Aberjona property are presented in Tables 3-7.1 and 3-7.2 for current and future land use, respectively. The current and future ILCRs are calculated assuming incidental ingestion of and dermal contact with surface soil. The total receptor RME and CTE ILCRs are presented in Tables 3-9.1 and 3-9.6 for current and future land use, respectively. The total receptor RME ILCRs for the current and future adult commercial worker are estimated to be within the target risk range of 10^{-6} to 10^{-4}. The total receptor CTE ILCRs for the current and future adult commercial worker are both estimated to be below 10^{-6}. The future vapor intrusion pathway will require further evaluation if a change in usage of the existing commercial building is contemplated that would result in higher occupancy (e.g., daycare use of the building), or as part of new building construction including any addition to the existing building. Use of a vapor barrier or subslab system may be appropriate to mitigate the vapor intrusion pathway in instances of future development/construction of occupied buildings.

Older Child Trespasser. The estimated ILCRs for the older child trespasser at the Aberjona property are provided in Tables 3-7.4 for future land use. Current and future ICLRs are calculated assuming incidental ingestion of and dermal contact with surface soil assuming unlimited access to the property in the future. The total receptor ICLR is presented in Tables 3-9.7. The total receptor RME ILCR is within the target risk range of 10^{-6} to 10^{-4} for the older child trespasser while the CTE ILCR is below 10^{-6}.

Young Child/Adult Recreational User. The future recreational user was evaluated for exposures to surface soil and subsurface soil. Surface soil exposures assume that the soils are not disturbed in the future. Subsurface soil exposures assume that future site use results in the relocation of subsurface soil to the surface. Estimated adult and young child ILCRs are summed to present total receptor cancer risk.

The estimated ILCRs for the future adult and young child recreational user exposed to media including surface soil are provided in Tables 3-7.7 and 3-7.8, respectively. ILCRs are calculated assuming incidental ingestion of and dermal contact with surface soil. The total receptor RME

and CTE ICLRs for the media evaluated are presented in Table 3-9.8. The total receptor RME and CTE ILCRs for the future young child and adult recreational user for surface soil exposure are within the target risk range of 10^{-6} to 10^{-4}.

The estimated ILCRs for the future adult and young child recreational user exposed to subsurface soil are provided in Table 3-7.7 and 3-7.8. ILCRs are calculated assuming incidental ingestion of and dermal contact with subsurface soil. The total receptor RME and CTE ICLRs for the media evaluated are presented in Table 3-9.9. The total receptor RME ILCR for the future young child and adult recreational user for subsurface exposure is within the target risk range of 10^{-6} to 10^{-4}. The total receptor CTE ILCR is below the target risk range.

Construction Worker. The future construction worker was evaluated for exposures to surface soil and subsurface soil. Subsurface soil risk was evaluated in combination with inhalation of outdoor trench air attributable to contaminated subsurface soil and groundwater, as well as incidental ingestion of and dermal contact with shallow groundwater.

The estimated ILCRs for the future construction worker exposed to surface soil are provided in Table 3-7.9. ILCRs are calculated assuming incidental ingestion of and dermal contact with surface soil and inhalation of particulates from surface soil. The total receptor RME and CTE ILCRs are presented in Table 3-9.10. The total receptor RME and CT ILCRs for the future construction worker exposed to surface conditions are below 10^{-6}.

The estimated ILCRs for the future construction worker exposed to subsurface soil and other media are provided in Table 3-7.9. ILCRs are calculated assuming incidental ingestion of and dermal contact with subsurface soil; inhalation of particulates associated with subsurface soil; inhalation of outdoor trench air attributable to contaminants in subsurface soil and groundwater; and incidental ingestion of and dermal contact with shallow groundwater. The total receptor RME and CTE ILCRs are presented in Table 3-9.11. The total receptor RME ILCR for the future construction worker is within the target risk range of 10^{-6} to 10^{-4}. The total receptor CTE ILCR is below the target risk range.

Existing Aberjona Residence. The estimated ILCRs for the current and future young child and adult resident exposed to vapor intrusion pathway VOCs in indoor air at the existing Aberjona residence are provided in Appendix D, Tables 7.1 through 7.4. For this scenario, ILCRs are calculated assuming inhalation of indoor air VOCs only. The cumulative risks for adults and children combined are presented in Appendix D, Tables 9.1 and 9.2. The total receptor RME ILCRs are within the target risk range of 10^{-6} to 10^{-4}. The total receptor CTE ILCRs are below the target risk range. Naphthalene, chloroform and TCE are the contributors to the ILCRs.

Though naphthalene was detected in shallow groundwater upgradient of the existing Aberjona residence, it was only detected in one of eight monitoring wells (AB-201) at a low concentration (9.49 µg/L). This monitoring well is not located in the vicinity of the existing Aberjona residence. In addition, naphthalene was only detected once at a low estimated concentration in the soil gas beneath the building (0.21 J ug/m^3). Therefore, naphthalene is likely present in indoor air due to an indoor source. Though TCE, PCE and chloroform were not found at significant concentrations for resident exposure in any indoor air samples, subslab soil gas concentrations of these compounds are greater than EPA soil gas screening levels (EPA, 2013a) for residential properties, with the subslab soil gas concentrations of TCE being the most elevated. The presence of elevated concentrations of VOCs, in particular TCE, in subslab soil gas beneath the existing Aberjona residence indicates a potential for future vapor intrusion to occur if building conditions were to change.

Whitney Property[7]

Adult Commercial Worker. The estimated ILCRs for the adult commercial worker are provided in Tables 3-7.1 and 3-7.2 for current and future land use, respectively. Current and future ILCRs are calculated assuming incidental ingestion of and dermal contact with surface soil. The total receptor RME and CTE ILCRs are presented in Tables 3-9.2 and 3-9.12 for current and future

[7] Worker protective measures should be used if excavation work is performed prior to remedy implementation near the rear of the building in the vicinity of the drain line connecting the former Whitney drum storage area to the municipal sewer system. During test pit excavation activities in this area in 2011, odors were observed and workers were outfitted with half-faced respirators with organic vapor cartridges due to elevated VOC readings.

land use, respectively. The total receptor RME and CTE ILCRs the current and future commercial worker are within the target risk range of 10^{-6} to 10^{-4}. The future vapor intrusion pathway will require further evaluation if a change in usage of the existing commercial building is contemplated that would result in higher occupancy (e.g., full-time commercial use of the building), or as part of new building construction including any addition to the existing building. Use of a vapor barrier or subslab system may be appropriate to mitigate the vapor intrusion pathway in instances of future development/construction of occupied buildings.

Older Child Trespasser. The estimated ILCRs for the older child trespasser are provided in Tables 3-7.3 and 3-7.4 for current and future land use, respectively. Current and future ICLRs are calculated assuming incidental ingestion of and dermal contact with surface soil. The total receptor RME and CT ILCRs are presented in Tables 3-9.3 and 3-9.13, respectively. The total receptor RME and CTE ILCRs for the current and future receptor are within the target risk range of 10^{-6} to10^{-4}.

Young Child/Adult Recreational User. The future recreational user was evaluated for exposures to surface soil and subsurface soil. Surface soil exposures assume that the soils are not disturbed in the future. Subsurface soil exposures assume that future site use results in the relocation of subsurface soil to the surface. Estimated adult and young child ILCRs are summed to present total receptor cancer risk.

The estimated ILCRs for the future adult and young child recreational user exposed to surface soil are provided in Tables 3-7.7 and 3-7.8, respectively. ILCRs are calculated assuming incidental ingestion of and dermal contact with surface soil. The total receptor RME and CTE ILCRs are presented in Table 3-9.14. The total receptor RME ILCR of 2×10^{-4} for the future child and adult recreational user exposed to surface soil exceeds 10^{-4} due to direct contact with surface soil. Compounds that contribute significantly to the RME ILCR in excess of 10^{-4} include: vinyl chloride , benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, indeno(1,2,3-cd)pyrene, dibenz(a,h)anthracene, total PCBs, PCB TEQ, chromium (VI) and arsenic. The CTE ICLR is within the target risk range.

The estimated ILCRs for the future adult and young child recreational user exposed to subsurface soil are provided in Tables 3-7.7 and 3-7.8, respectively. ILCRs are calculated assuming incidental ingestion of and dermal contact with subsurface soil. The total receptor RME and CTE ILCRs are presented in Table 3-9.15. The total receptor RME ILCR of 1 x 10^{-3} for the future child and adult recreational user exposed to subsurface conditions exceeds 10^{-4} due to direct contact with subsurface soil. Compounds that contribute significantly to the RME ILCR in excess of 10^{-4} include: vinyl chloride, trichloroethene, bis(2-ethylhexyl)phthalate, benzo(a)pyrene, dibenz(a,h)anthracene, alpha-chlordane, gamma-chlordane, alpha-BHC, heptachlor, heptachlor epoxide, dieldrin, 4,4'-DDD, 4,4'DDT, total PCBs, PCB TEQ, chromium (VI) and arsenic. The CTE ICLR is within the target risk range.

Construction Worker. The future construction worker was evaluated for exposures to surface soil and subsurface soil. Subsurface soil risk was evaluated in combination with inhalation of outdoor trench air attributable to contaminated subsurface soil and groundwater, as well as incidental ingestion of and dermal contact with shallow groundwater.

The estimated ILCRs for the future construction worker exposed to surface soil and other media are provided in Table 3-7.9. ILCRs are calculated assuming incidental ingestion of and dermal contact with surface soil and inhalation of particulates associated with surface soil. The total receptor RME and CT ILCRs are presented in Table 3-9.16. The total receptor RME and CTE ILCRs for the future construction worker exposed to surface conditions are within or below the target risk range of 10^{-6} to 10^{-4}.

The estimated ILCRs for the future construction worker exposed to subsurface soil and other media are provided in Table 3-7.9. ILCRs are calculated assuming incidental ingestion of and dermal contact with subsurface soil; inhalation of particulates associated with subsurface soil; incidental ingestion of and dermal contact with shallow groundwater; and inhalation of outdoor trench air attributable to contaminants in subsurface soil and groundwater. The total receptor RME and CTE ILCRs are presented in Table 3-9.17. The total receptor RME and CTE ILCRs for the future construction worker exposed to subsurface conditions are within target risk range of 10^{-6} to 10^{-4}.

Murphy Property

Adult Commercial Worker. The estimated ILCRs for the adult commercial worker are provided in Tables 3-7.1 and 3-7.2 for current and future land use, respectively. Current and future land use ILCRs are calculated assuming incidental ingestion of and dermal contact with surface soil. The total receptor RME and CTE ILCRs are presented in Tables 3-9.4 and 3-9.18 for current and future land use, respectively. The total receptor RME and CTE ILCRs for current and future adult commercial worker are within or below the target risk range of 10^{-6} to 10^{-4}. The future vapor intrusion pathway will require further evaluation if a change in usage of the existing commercial building is contemplated that would result in higher occupancy (e.g., full-time commercial use of the building), or as part of new building construction including any addition to the existing building. Use of a vapor barrier or subslab system may be appropriate to mitigate the vapor intrusion pathway in instances of future development/construction of occupied buildings.

Older Child Trespasser. The estimated ILCRs for the future older child trespasser are provided in Table 3-7.4. Future ICLRs are calculated assuming incidental ingestion of and dermal contact with surface soil. The total receptor ILCRs are presented in Table 3-9.19. The total receptor RME and CTE ILCRs for the future older child trespasser are within or below the target risk range of 10^{-6} to 10^{-4}.

Young Child/Adult Recreational User. The future recreational user was evaluated for exposures to surface soil and subsurface soil. Surface soil exposures assume that the soils are not disturbed in the future. Subsurface soil exposures assume that future site use results in the relocation of subsurface soil to the surface. Estimated adult and young child ILCRs are summed to present total receptor cancer risk.

The estimated ILCRs for the adult and young child future recreational user exposed to surface soil and other media are provided in Tables 3-7.7 and 3-7.8, respectively. ILCRs are calculated

assuming incidental ingestion of and dermal contact with surface soil. The total receptor ILCRs are presented in Table 3-9.21. The total receptor RME and CT ILCRs for the future recreational user exposed to surface conditions are within the target risk range of 10^{-6} to10^{-4}.

The estimated ILCRs for the future adult and young child recreational user exposed to subsurface soil and other media are provided in Tables 3-7.7 and 3-7.8, respectively. ILCRs are calculated assuming incidental ingestion of and dermal contact with subsurface soil. The total receptor RME and CTE ILCRs are presented in Table 3-9.23. The total receptor RME and CTE ILCRs for the future recreational user exposed to subsurface conditions are within or below the target risk range of 10^{-6} to 10^{-4}.

Construction Worker. The future construction worker was evaluated for exposures to surface soil and subsurface soil. Subsurface soil risk was evaluated in combination with inhalation of outdoor trench air attributable to contaminated subsurface soil and groundwater, as well as incidental ingestion of and dermal contact with shallow groundwater.

The estimated ILCRs for the future construction worker exposed to surface soil and other media are provided in Table 3-7.9. ILCRs are calculated assuming incidental ingestion of and dermal contact with surface soil and inhalation of particulates associated with surface soil. The total receptor RME and CTE ILCRs are presented in Table 3-9.24. The total receptor RME and CTE ILCRs for the future construction worker exposed to surface conditions are less than the target risk range.

The estimated ILCRs for the future construction worker exposed to subsurface soil and other media are provided in Table 3-7.9. ILCRs are calculated assuming incidental ingestion of and dermal contact with subsurface soil; inhalation of particulates associated with subsurface soil; incidental ingestion of and dermal contact with shallow groundwater and inhalation of outdoor trench air attributable to contaminants in subsurface soil and groundwater. The total receptor RME and CTE ILCRs are presented in Table 3-9.25. The total receptor RME and CTE ILCRs for the future construction worker exposed to subsurface conditions are within the target risk range of 10^{-6} to 10^{-4}.

Murphy Wetland

The Murphy Wetland is evaluated as a separate exposure point for the current and future trespasser and for the future recreational user. Typically, risks associated with surface water and sediment would be evaluated in combination with other Site media. However, due to the location of the Murphy Wetland (i.e., located between the upland portions of the Murphy, Whitney, Wildwood and Aberjona properties), the wetland area is being evaluated as a separate exposure point. Ingestion of surface water is assumed to not be an exposure pathway and was, therefore, not evaluated. Dermal absorption of chromium from surface water was assumed to be a potential exposure pathway.

Older Child Trespasser. The estimated ILCRs for the older child trespasser exposed to sediment in the Murphy Wetland are provided in Tables 3-7.3 and 3-7.4 for current and future land use, respectively. ILCRs are calculated assuming incidental ingestion of and dermal contact with sediment. The total receptor RME and CTE ILCRs are presented in Tables 3-9.5 and 3-9.20. The total receptor RME and CTE ILCRs for the current and future trespasser are within the target risk range of 10^{-6} to 10^{-4}. Risk associated with dermal absorption of chromium from surface water was within the target risk range.

Young Child/Adult Recreational User. The estimated ILCRs for the future adult and young child recreational user exposed to sediment in the Murphy Wetland are provided in Tables 3-7.7 and 3-7.8, respectively. ILCRs are calculated assuming incidental ingestion of and dermal contact with sediment. The total receptor RME and CTE ILCRs are presented in Table 3-9.22. The total receptor RME and CTE ILCRs for the future recreational user are within the target risk range of 10^{-6} to 10^{-4}.

Site-Wide Future Resident Tap Water Use

The estimated ILCRs for the future site-wide adult and young child resident are provided in Tables 3-7.5 and 3-7.6, respectively. ILCRs are calculated assuming ingestion of groundwater,

dermal contact with groundwater during household water use, and inhalation of volatiles released from water during household water use. The total receptor RME and CTE ILCRs are presented in Table 3-9.26. The adult and child ILCRs are summed to present the total receptor cancer risk. The RME and CTE ILCRs of 3×10^{-1} and 6×10^{-3}, respectively, for the future resident are above 10^{-4}. Compounds that contribute significantly to the RME ILCR in excess of 10^{-4} include: benzene, 1,4-dichlorobenzene, 1,1-dichloroethane, 1,2-dichloroethane, 1,4-dioxane, 1,1,2-trichloroethane, ethylbenzene, methyl tert-butyl ether, methylene chloride, tetrachloroethene, 1,2,4-trichlorobenzene, trichloroethene, vinyl chloride, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, naphthalene, indeno(1,2,3-cd)pyrene, PCB TEQ, total PCBs, 4,4'-DDD, 4,4'-DDT, aldrin, alpha-BHC, alpha-chlordane, beta-BHC, dieldrin, lindane, gamma-chlordane, heptachlor, heptachlor epoxide and arsenic. Compounds that contribute significantly to the CTE ILCR in excess of 10^{-4} include: benzene, 1,4-dichlorobenzene, 1,1-dichloroethane, 1,4-dioxane, 1,2,4-trichlorobenzene, trichloroethene, vinyl chloride, benzo(a)pyrene, naphthalene, PCB TEQ, total PCBs, aldrin, alpha-BHC, heptachlor and arsenic.

Though the 2011 and 2013 groundwater sampling data have been used in place of the 2002 sampling data, a similar though somewhat more extensive list of risk-contributing chemicals has been identified using the 2011/2103 data set than was identified in the 2006 baseline risk assessment. The more extensive list of groundwater risk-contributors is due to changes in toxicity values and the more analytically comprehensive data set available for use which reduces the uncertainty associated with the baseline risk assessment.

3.5.2.3 Risks Associated with Exposure to Lead

Lead was selected as a COPC for soil and sediment. Childhood lead exposures were evaluated through use of the IEUBK model (EPA, 1994b; 2007). Adult lead exposures were evaluated using the methodology provided by EPA (2003a; 2009a). The results of the lead evaluation for all three properties are contained in Appendix B.6. For adult exposures for soil and sediment, the calculated central estimate of the blood lead concentration in women of childbearing age did not exceed the goal of 4.2 μg/dL for current and future land use. Likewise, assumed childhood lead exposures to soil were not estimated to result in blood lead levels exceeding the goal of 10

µg/dL. However, the lead evaluation for sediment in the Murphy Wetland indicates that future young child recreational exposures could result in childhood blood lead levels in excess of blood lead level goals. The highest lead concentrations in the Murphy wetland are located at sampling locations SW-2 (35,100 mg/kg), P-12 (24,900 mg/kg), P-14 (16,800 mg/kg), MR-11 (12,000 mg/kg) and P-43 (11,100 mg/kg). The elevated lead levels in sediment may be related to elevated lead concentrations in shallow groundwater in the vicinity of monitoring wells MW-24, MW-16 and MW-18S which displayed the groundwater lead concentrations in excess of the Safe Drinking Water Act (SDWA) action level of 15 micrograms per liter (µg/L) (129 µg/L, 36.2 µg/L and 16.8 µg/L, respectively) and are located within or adjacent to the Murphy Wetland Because the maximum concentration of lead detected in groundwater (129 µg/L) exceeds the SDWA action level, further evaluation may be required.

3.5.2.4 Soil Background Discussion

Six background surface and subsurface soil samples (AB-5, AB-10, AB- 17, WB-14, MR-19, and MR-18) were collected from locations that were outside of the areas of impact at the three properties. In addition, two background groundwater samples (MW-1 and MW-2) were collected from a location upgradient of the three properties. Soil samples were analyzed for metals only and groundwater samples were analyzed for VOCs, SVOCs, VPH, EPH, dioxin-like PCB congeners, metals (including hexavalent chromium), and cyanide. The background data are presented in Appendix B.1.

Background surface and subsurface soil data for arsenic were compared to the soil data for the Whitney property where arsenic was identified as a risk contributor. The comparison indicates that the concentrations of arsenic in surface soils at the Whitney property (2.27 mg/kg to 15 mg/kg) are comparable to the background surface soil concentrations (6.2 mg/kg to 12 mg/kg). However, arsenic in subsurface soil at the Whitney property (1.2 mg/kg to 140 mg/kg) were substantially greater than those in background subsurface soil (3.6 mg/kg to 7.42 mg/kg). Thus, background conditions contribute to the calculated site-related risks associated with exposure to surface soil arsenic at the Whitney property. Significantly elevated concentrations of arsenic in subsurface soil at the Whitney property were located at sampling location WB-201 (110 mg/kg at

3-5’ and 140 mg/kg at 5-6’). Other Whitney property subsurface soil sampling locations had concentrations within the range of background concentrations or slightly greater than the background range. Site-wide groundwater COPCs concentrations were consistently greater than concentrations detected in the background wells.

Background surface and subsurface sol data for thallium were compared to soil data for the Murphy property where thallium was identified as a risk contributor. Thallium was not detected in background soils with reporting limits ranging from 0.14 mg/kg to 0.16 mg/kg. Thallium was detected in surface soil at concentrations ranging from 0.054 mg/kg to 10 mg/kg, and in subsurface soil from 0.069 mg/kg to 30 mg/kg. Five locations (one surface soil location; 4 subsurface soil locations) have thallium concentrations above the non-detect background levels identified for soil (B-18 [0-2’], B-10 [6-10’ and 10-14’], B-5 [13-15’], B-8 [7-8’ and 8-12’] and B-9 [6-10’]). Therefore, it appears that thallium at these Murphy property surface and subsurface locations are not associated with background conditions at the site.

3.5.3 Description of Uncertainties

Estimation of risks to human health that may result from exposure to chemicals in the environment is a complex process that often requires the combined efforts of multiple disciplines. Each exposure assumption and chemical toxicity value has a degree of variability and uncertainty associated with it. In each step of the risk assessment process, beginning with the data collection and analysis and continuing through the toxicity assessment, exposure assessment, and risk characterization, conservative assumptions are made that are intended to be protective of human health and to ensure that risks are not underestimated. The following subsections provide a discussion of the key uncertainties that may affect the final estimates of human health risk in this risk assessment. Uncertainties are arranged by topic.

3.5.3.1 Environmental Sampling

Environmental samples are collected to characterize the average concentration of contaminants that an individual may contact over time. Sampling-related uncertainties include: limitations on

sample size as well as sampling procedures. Sample size is limited by resources and, therefore, a conservative estimate of the average concentration is used. The sample size, combined with a conservative estimate of the mean contaminant concentration, may over- or underestimate the true concentration of contamination that an individual contacts over time. Sampling procedures require use of a very small amount of material to represent a much greater area which also contributes to uncertainty.

At the Southwest Properties these uncertainties are likely to be minimal since the primary areas of contamination (i.e., the source areas) have been well characterized through multiple sampling events as well as selection of sampling locations based on available information on past operations at the Southwest Properties.

More COPCs and risk-contributing chemicals were identified in this baseline risk assessment than identified in the 2006 baseline risk assessment. The increase in soil COPCs and risk-contributors is likely due changes in toxicity values and the additional sampling conducted in 2010 and 2011 to more accurately characterize potential source areas at each of the properties. Though the 2011 and 2013 groundwater sampling data have been used in place of the 2002 sampling data, a similar though somewhat more extensive list of COPCs and risk-contributing chemicals has been identified using the 2011/2013 data set than was identified in the 2006 baseline risk assessment. The more extensive list of groundwater risk-contributors is due to changes in toxicity values and the more analytically comprehensive data set available for use which reduces the uncertainty associated with the baseline risk assessment.

Another measure taken to reduce the uncertainty associated with site data was the collection of site-specific chromium speciation (chromium VI) data for soil, sediment and groundwater. This data was used to more accurately characterize risk associated with chromium exposures at the Site.

With respect to determining exposure point concentrations for this evaluation, contaminant concentrations in groundwater were assumed to remain constant over time. This assumption may contribute to overestimating risks, depending on the degree of chemical degradation or

transport to other media. Conversely, biodegradation of chemicals to more toxic chemicals would contribute to an underestimation of risk. However, recent sampling was conducted and use preferentially over historical data for groundwater to minimize the uncertainty associated with biodegradation.

There is also uncertainty associated with the indoor air sampling at the exsiting Aberjona residence. Since it is not possible to continuously sample the indoor air of a building, two or more samples were taken from the building on a given day and the results were considered to be representative of the VOCs present in indoor air throughout the building over time. To try to reduce this uncertainty, two rounds of indoor air sampling were conducted for the building, one during the heating season and one during the cooling season.

3.5.3.2 Analytical Data Quality

Data quality measures were in place to ensure that data are appropriate for use in the risk assessment. Data validation procedures were followed to minimize potential errors in identification and quantification of contaminants and to ensure that only data of known and documented quality were used. The data validation reports that summarize laboratory performance, and potential biases on the data, are included in RETEC's Draft RI Report (RETEC, 1994), the Supplemental RI (RETEC, 2003) and TRC's Split Sample Report (TRC, 2004). A data validation report will be provided for the 2010/2011/2013 AECOM supplemental data set when the supplemental RI report is issued.

Due to uncertainty of quantification, individual chemicals were sometimes listed as detected, but with the concentration qualified as "estimated" in accordance with data validation procedures. The estimated value was used in the risk assessment. In some cases, analytical errors or sampling errors resulted in the rejection of data, which decreased the amount of data available and increased uncertainty associated with the representativeness of the detected chemical concentrations.

In addition, the contaminant concentrations reported as non-detected may actually range from non-detect (i.e., not present) up to the value of the SQL. The replacement of non-detects with a value equal to one-half the SQL for the calculation of the arithmetic mean is intended to be reasonably conservative, but could over- or underestimate the actual constituent concentrations present in the environmental media. Elevated SQLs were reported for some constituent analytical results, which may mask the presence of that constituent in the affected samples. This may result in an underestimation of risk. One chemical for which this may have occurred is 1,4-dioxane. All results for this chemical were non-detect in soil, therefore, it was not quantitatively evaluated in the risk assessment. Soil SQLs for this chemical range from 0.041 mg/kg to 460 mg/kg, compared to a residential soil RSL of 4.9 mg/kg and a commercial soil RSL of 17 mg/kg. Therefore, excluding this chemical from the quantitative assessment could have resulted in an underestimation of the risk, if 1,4-dioxane was present at concentrations greater than the RSL. However, all locations with elevated SQLs were located on the Whitney property where risks calculated for soils were above EPA risk management criteria. In groundwater, a number of 2011 non-detect results for 1,4-dioxane were rejected. The maximum detected concentration (78 µg/L) was used as the EPC for the RME scenario, potentially resulting in an underestimation of risk if the presence of higher concentrations of 1,4-dioxane in groundwater was masked by the rejected data. However, use of the maximum detected concentration results in the conclusion that 1,4-dioxane is a risk contributor in groundwater. Therefore, the conclusions of the risk assessment have not been affected by the rejected groundwater data and elevated SQLs for 1,4-dioxane, though the potential extent of 1,4-dioxane in groundwater and soil cannot be accurately determined based on the available data.

3.5.3.3 Selection of Chemicals for Evaluation

The maximum detected chemical concentrations or modeled concentrations in surface soil, subsurface soil, groundwater, outdoor trench air, indoor air, sediment and surface water were compared to one or more of the following screening criteria: EPA RSLs, AWQC and MCLs. Chemicals whose maximum concentrations were below their respective cancer screening value or 10-percent of their noncancer screening value were not carried through the assessment. It is unlikely that this risk-based screening excluded chemicals that would be of concern, based on the

conservative exposure assumptions and conservatively derived toxicity criteria that are the basis of the screening criteria. Although following this methodology does not provide a quantitative risk estimate for all chemicals, it focuses the assessment on the chemicals accounting for the greatest risks (i.e., chemicals whose maximum concentrations exceeded their respective screening value), and, although the overall risk estimates are uncertain, it is not expected that actual risks will be significantly greater than estimated risks.

In addition, VOCs in indoor air that were determined to be present as a result of a background indoor source, unrelated to the VI pathway, were not quantitatively evaluated. Some of these VOCs that were not related to the VI pathway exceeded residential air RSLs and may be associated with increased risk to building occupants. Other indoor sources of VOCs may be investigated and addressed by building occupants to reduce the risk associated with the presence of VOCs from indoor sources (e.g., hobbies, cleaning products, fuel oil leakage).

3.5.3.4 Toxicological Data

Uncertainty is associated with the toxicity values and toxicity information available to assess potential adverse effects.

Chronic RfDs are used to assess the potential for noncancer effects. Chronic RfDs represent an estimate (with uncertainty spanning perhaps an order of magnitude or greater) of a daily exposure level for the human population, including sensitive subpopulations, that is likely to be without an appreciable risk of deleterious effects during a lifetime.

The cancer slope factor, or CSF, and the unit risk , or UR, are plausible upper bound estimates of carcinogenic potency used to calculate cancer risk from exposure to carcinogens, by relating estimates of lifetime average chemical intake or exposure to the incremental probability of an individual developing cancer over a lifetime. The CSFs and URs developed by the USEPA are plausible upper bound estimates, which means that the EPA is reasonably confident that the actual cancer risk will not exceed the estimated risk calculated using the CSF or UR.

For dermal exposure pathways, the absence of dermal toxicity criteria necessitated the use of oral toxicity data. To calculate risk estimates for the dermal pathway, absolute oral bioavailability factors that reflect the toxicity study conditions were used to modify the oral toxicity criteria. For the chemicals with oral absorption exceeding 50-percent, a default oral absorption factor of 100-percent was used. The risk estimates for the dermal pathways may be over- or underestimated depending on how closely these values reflect the difference between the oral and dermal routes.

Cancer risk estimates for dioxin-like PCB congeners were calculated using cancer toxicity values developed by CalEPA (CSF of 1.3E+05 $[mg/kg\text{-}day]^{-1}$). In 1985, EPA published a CSF for dioxins of 1.56E+05 $(mg/kg\text{-}day)^{-1}$ which is about 20% more conservative than the CalEPA value. Use of the higher 1985 EPA CSF would have resulted in higher risk estimates associated with dioxin-like PCBs. However, the increased risks on the Murphy and Aberjona properties would not have been of a sufficient magnitude to alter the conclusions of the risk assessment. Dioxin-like PCBs are already identified as risk contributors in Whitney property soil, Murphy Wetland sediment and groundwater. EPA is currently in the process of re-evaluating the toxicity of dioxins and the most current information will be used to develop cleanup values for the site.

3.5.3.5 Exposure Assessment

There are uncertainties associated with the exposure point concentration (EPC), the exposure scenarios selected and the individual exposure parameters used for each scenario. The uncertainties associated with these various sources are discussed below.

Conservative estimates of the EPC were based on measured concentration of contaminants on the site, except for estimates of outdoor trench air concentrations during construction as described below. EPA's software program, ProUCL, which has been widely reviewed, was used to determine 95-percent UCLs of the mean concentration of COPCs. ProUCL is a comprehensive statistical software program that has goodness-of-fit tests for normal, lognormal, and gamma distributions for data sets with and without ND observations. ProUCL also provides parametric and nonparametric methods to compute upper confidence limits (UCLs) of mean

concentrations. Use of ProUCL to conservatively estimate the mean is unlikely to underestimate the exposure concentration.

In the absence of monitoring data, a fate and transport model was used for the evaluation of exposure to outdoor trench air for the construction worker to estimate volatilization of COPCs from soil and groundwater. The version of the model used property-specific information such as the minimum observed depth to groundwater. The assumptions used in the model are conservative and tend to overestimate health risks.

The exposure scenarios selected for this evaluation include the CTE and RME scenarios. The RME assumptions were selected to provide an upper-bound of estimate of exposure in accordance with EPA guidance regarding avauation of potential exposures at Superfund sites. Therefore, exposures and estimated risks for the majority of the evaluated receptors are likely to be overestimated. For example, the exposure time assumed for the RME residential scenario in this analysis is 24 hours per day. It is likely that residential exposure occur less frequently than assumed, which may result in an overestimate of risk.

3.5.3.6 Risk Characterization

The uncertainties associated with the risk characterization may be categorized into two groups: 1) those related to the other components of the risk assessment (i.e., the hazard identification, dose response assessment, and exposure assessment) and 2) those inherent in the risk characterization methodologies. The key uncertainty associated with the latter category is the assumption that constituent-specific risks are additive (i.e., act independently (1 + 1 = 2)). This oversimplifies the fact that constituents may also act synergistically (1 + 1 > 2) or antagonistically (1 + 1 < 2). The nature of the impact of the assumption of additivity on the risk estimates for the site is unknown. However, as a guide, if compounds act synergistically, then assuming additivity would underestimate risk; if they act antagonistically, then risk would be overestimated.

As recommended in RAGS Part E (EPA, 2004b), select COPCs in water were not assessed for their contribution to risk via the dermal absorption phase due to permeability constants that were beyond the effective predictive domain. These compounds include carcinogenic PAHs, total PCBs, PCB TEQ and DDT. The lack of evaluation of the dermal water pathway for these compounds likely underestimates the risk associated with construction worker exposures to shallow groundwater and future residential exposures to groundwater used as household water. The permeability constants for chlorinated VOCs in groundwater (e.g., cis-1,2-dichloroethene, trichloroethene, tetrachloroethene and vinyl chloride) are likely overestimated and therefore, overestimate the risk for these two receptor populations.

Cancer risks and HIs for each receptor were not summed across all media. For example, the risks to the recreational and trespasser receptors from surface water and sediment were not summed with those from soil ingestion and dermal contact for the three properties. This may have resulted in an underestimation of cumulative risk for these receptors. However, summing the risks for all pathways in this circumstance will not have a significant impact on the overall calculated risks because the risk associated with exposure to sediments is significantly greater than for exposure to soil. In addition, risks from a given medium were not summed across exposure areas (e.g. soil media across Aberjona Property, Whitney Property and Murphy Property). That is, for any given receptor, risks were calculated assuming that exposure occurs at only one property. This assumption is uncertain since a given recreational receptor may spend half his/her time in one exposure area and half in another. Risks to such an individual would be intermediate between the risks to individuals exposed solely within each exposure area.

Arsenic was selected as a contributor to the cancer risk for the future recreational user at the Whitney property due to ingestion of, and dermal contact with surface and subsurface soil. The total RME cancer risk for this scenario was $2x10^{-4}$ for surface soil and $7x10^{-4}$ for subsurface soil. Arsenic's contribution to the total cancer risk is $3x10^{-6}$ for surface soil and $1x10^{-5}$ for subsurface soil. Based on the previous background discussion, potential historical releases of arsenic in surface soil at the Whitney property cannot be distinguished from background and therefore, arsenic is not considered to be a major contributor to risk for this property. However, arsenic in subsurface soil at location WB-201 (3-5' and 5-6') are significantly elevated above background

subsurface soil concentrations. Therefore, the arsenic concentrations at this location appear to be attributable to a site-related release rather than associated with a background condition.

3.5.3.7 Overall Uncertainty

This risk assessment contains many layers of conservative assumptions and therefore tends to overestimate rather than underestimate risk.

3.5.4 Summary of Human Health Risks

Overall summaries of cancer and noncancer risks estimates for each of the evaluated scenarios and pathways and for each exposure point are presented in Tables 3-9.1 through 3-9.26 and Appendix D, Tables 9.1 and 9.2, for the vapor intrusion indoor air pathway at the existing Aberjona residence. Contaminants contributing to total receptor ILCRs and HIs in excess of 10^{-4} and 1, respectively, are presented in Tables 3-10.1 through 3-10.7. Risks are summarized for both the RME and CTE receptors. When risks were estimated for a child and adult receptor, the child HIs are presented as the most conservative, while incremental lifetime cancer risks (ILCRs) are the sum of the child and adult risks (i.e., a total receptor cancer risk). For all media except surface water and sediment, the risks presented by exposure point have been summed together under the assumption that each receptor is exposed to all applicable media during site activities. The Murphy Wetland was evaluated as a separate exposure point because of its location (i.e., located between the upland portions of the Murphy, Whitney, Wildwood and Aberjona properties). The existing Aberjona residence was also evaluated as a separate exposure point for the vapor intrusion indoor air pathway.

When a receptor-specific HI for an exposure medium exceeded 1, HIs were segregated by target organ and discussed as to whether target organ-specific HIs exceed the risk management criterion. Estimated ILCRs were compared to the EPA target risk range of 10^{-6} to 10^{-4}. Risks were not summed across the properties since the parameter values used assume maximal exposures within each exposure area. This approach assumes that an individual would not be maximally exposed to media at more than one property.

The following summarizes the major risk contributors (HI >1, ILCR >10^{-4}) for the evaluated pathways and media for each of the three properties, the Murphy Wetland, the existing Aberjona residence and the future site-wide resident tap water pathway. Other contaminants that contribute to risk at the site below these thresholds are discussed in 3.5.2. This summary focuses on the major risk contributors.

Lead in soil and sediment was evaluated through the use of EPA models for children and adults. For adult exposures to soil and sediment, the calculated central estimate of the blood lead concentration in women of childbearing age did not exceed the goal of 4.2 μg/dL for current and future land use. Likewise, assumed childhood lead exposures to soil were not estimated to result in blood lead levels exceeding the goal of 10 μg/dL. Therefore, lead in soil was determined not to be of concern for human receptors at the Southwest Properties. Lead in groundwater was evaluated by comparing monitoring well concentrations to the Safe Drinking Water Act (SDWA) action level of 15 micrograms per liter (μg/L).

Aberjona Property. The ILCRs and HIs are all below risk management criteria for all scenarios evaluated.

Whitney Property[8]. The RME and/or CTE ILCR and/or HI exceed the target risk range for the future recreational user and future construction worker. Major risk contributors for the recreational user are direct contact with benzo(a)pyrene and total PCBs in surface soil and heptachlor, total PCBs and PCB TEQ in subsurface soil. The major risk contributors for the construction worker exceedances are total PCBs and PCB TEQ in subsurface soil and cis-1,2-dichloroethene, tetrachloroethene and trichloroethene in shallow groundwater.

[8] Worker protective measures should be used if excavation work is performed prior to remedy implementation near the rear of the building in the vicinity of the drain line connecting the former Whitney drum storage area to the municipal sewer system. During test pit excavation activities in this area in 2011, odors were observed and workers were outfitted with half-faced respirators with organic vapor cartridges due to elevated VOC readings.

Murphy Property. The ILCRs and HIs are all below risk management criteria for all scenarios and pathways evaluated, except for the future RME HI for the construction worker exposed to shallow groundwater and the future recreational user exposed to surface and subsurface soil. For the worker scenario, cis-1,2-dichloroethene in groundwater is the major risk contributing chemical. For the recreational user, thallium in soil is the major risk contributing chemical.

Murphy Wetland. The RME HI exceeds the target risk range for the future older child trespasser. The RME and CTE HIs were above the target HI of 1 for the future young child/adult recreational user. The major risk contributors for the future trespasser is total PCBs in sediment. The major risk contributors for the future recreational receptor are total PCBs and C11-C22 aromatics in sediment for the RME case and total PCBs in sediment for the CTE case. The lead evaluation for sediment indicates that future young child recreational exposures could result in childhood blood lead levels in excess of blood lead level goals. The highest lead concentrations are located at sampling locations SW-2 (35,100 mg/kg), P-12 (24,900 mg/kg), P-14 (16,800 mg/kg), MR-11 (12,000 mg/kg) and P-43 (11,100 mg/kg).

Existing Aberjona Residence. The ILCRs and HIs are all below risk management criteria for current and future young child and adult residents exposed to vapor intrusion pathway VOCs in indoor air at the existing Aberjona residence. Naphthalene and TCE are the primary contributors to the ILCRs and HIs.

Though naphthalene was detected in shallow groundwater upgradient of the existing Aberjona residence, it was only detected in one of eight monitoring wells (AB-201) at a low concentration (9.49 µg/L). This monitoring well is located approximately 200 feet from the existing Aberjona residence. In addition, naphthalene was only detected once at low estimated concentration in the soil gas beneath the building (0.21 J ug/m^3). Therefore, naphthalene is likely present in indoor air due to an indoor source. Though TCE, PCE and chloroform were not found at significant concentrations for resident exposure in any indoor air samples, subslab soil gas concentrations of these compounds are greater than EPA soil gas screening levels (EPA, 2013a) for residential properties, with the subslab soil gas concentrations of TCE being the most elevated. The presence of elevated concentrations of VOCs, in particular TCE, in subslab soil gas beneath the

existing Aberjona residence indicates a potential for future vapor intrusion to occur if building conditions were to change.

Site-Wide Future Resident Tap Water Use. The RME and CTE cancer and non-cancer risks exceed risk management criteria for the future site-wide resident exposed to groundwater during household use. The major risk contributors associated with RME exceedances are direct contact with benzene, 1,1-dichloroethane, cis-1,2-dichloroethene, trans-1,2-dichloroethene, 1,4-dioxane, methylene chloride, tetrachloroethene, 1,2,3-trichlorobenzene, 1,2,4-trichlorobenzene, 1,1,2-trichloroethane, trichloroethene, vinyl chloride, xylenes (total), C5-C8 aliphatics, C9-C12 aliphatics, C9-C10 aromatics, C9-C18 aliphatics, C11-C22 aromatics, 2-methylnaphthalene, naphthalene, PCB TEQ, total PCBs, aldrin, alpha-BHC, lindane, heptachlor, heptachlor epoxide, arsenic, cobalt, iron, and manganese. In the CTE case, cis-1,2-dichloroethene, 1,2,4-trichlorobenzene, 1,1,2-trichloroethane, trichloroethene, vinyl chloride, C9-C12 aliphatics, C9-C18 aliphatics, naphthalene, total PCBs, arsenic and manganese were the major risk contributors. In addition, the maximum concentration of lead detected in groundwater (129 µg/L) exceeds the SDWA action level. The elevated lead levels in Murphy Wetland sediment may be related to shallow groundwater concentrations in the vicinity of monitoring wells MW-24, MW-16 and MW-18S which displayed groundwater lead concentrations of 129 µg/L, 36.2 µg/L and 16.8 µg/L, respectively. These monitoring wells are located within or adjacent to the Murphy Wetland.

Should a change in land use at the Southwest Properties be contemplated that would include activities and uses not evaluated in the risk assessment, further evaluation will be required to assess the risks associated with the proposed land use change, including use of groundwater for purposes not identified in the risk assessment. In addition, the future vapor intrusion pathway will require further evaluation if a change in usage of any of the existing commercial buildings is contemplated that would result in higher occupancy (e.g., full-time commercial use of the Whitney or Murphy buildings or daycare use of the Aberjona building), or as part of new building construction including any addition to existing buildings on any of the properties. Use of a vapor barrier or subslab system may be appropriate to mitigate the vapor intrusion pathway in instances of future development/construction of occupied buildings.

NOTES:

Only detected compounds shown.

Shaded compounds were detected in shallow groundwater, soil gas and indoor air, indicating a potential vapor intrusion pathway.

(a) Though this compound may be present in indoor air due to vapor intrusion, the maximum detected concentration was below the risk-based screening value. Therefore, this compound is not an indoor air COPC.

Freon-113 = 1,1,2-Trichloro-1,2,2-trifluoroethane

SECTION 3 TABLES

(SEE VOLUME II)

4.0 ECOLOGICAL RISK ASSESSMENT

4.1 Introduction

The ERA describes existing habitats and ecological receptor species that have been noted or are expected to be present at the Site and evaluates the potential risks associated with the exposure of these biota to surface water, sediment, and surface soil contaminants detected during the site characterization. Site reconnaissance was conducted by TRC ecologists and supplements data provided in the RETEC Sampling and Analysis Plan, Supplemental Remedial Investigation. The objective of this risk assessment is to evaluate whether contaminants present within the Southwest Properties Study Area may pose adverse impacts to biota inhabiting the Site. The Site includes the three properties consisting of the Aberjona Auto Parts (Aberjona property), Whitney Barrel (Whitney property), and Murphy Waste Oil (Murphy property). A small wetland (Murphy Wetland) is present within the northwestern portion of the Site that contains areas of forested/scrub-shrub wetland and a seasonally ponded area. With the exception of the Murphy Wetland, no other significant habitat exists on the Site. Hence, only the Murphy Wetland and its associated habitat were evaluated under this ERA.

This ecological risk assessment was conducted in accordance with the following U.S. Environmental Protection Agency (EPA) guidance:

- Ecological Risk Assessment Guidance for Superfund: Process for Designing and Conducting Ecological Risk Assessments. EPA/540/R-97-006. June 1997 (EPA, 1997).
- Guidelines for Ecological Risk Assessment. EPA/630/R-958/002Fa. May 1998 (EPA, 1998a).

Following the guidelines prepared by the EPA, the basic components of the ecological risk assessment for the site are comprised of the following parts:

- Problem Formulation
    - Description of the Ecological Resource (Resource Characterization)

- Hazard Identification
- Site Conceptual Model
- Assessment Endpoints and Measurement Endpoints

- Analysis
  - Exposure Assessment
  - Ecological Effects Assessment

- Risk Characterization

This ERA provides introductory information in Section 4.1. Section 4.2 describes the ecological resources present at the Site, formulates the risk assessment problem including the presentation of a site conceptual model that includes the proposed assessment endpoints and measurement endpoints. Environmental samples used in the ERA and COPECs are also selected in this section as is a brief review of the ecotoxicity data for these constituents. Section 4.3 provides the ERA analysis including the evaluation of biota exposed to Site COPECs and an assessment of potential effects of these contaminants to various receptor organisms. Section 4.4 characterizes risk to ecological receptors inhabiting the Site and a summary and conclusions are presented in Section 4.5. References cited in the ERA are provided in Section 5.4.

4.2 Problem Formulation

Problem Formulation is comprised of two primary components: Resource Characterization and Hazard Identification. Resource Characterization describes habitats present at the Site and identifies potential receptor species. Hazard Identification discusses exposure pathways and identifies contaminants of ecological concern. The results of these components are then used to develop a conceptual model including the selection of assessment endpoints and measurement endpoints.

4.2.1 Resource Characterization

The approximate 13 acre Site is located adjacent to Salem Street in the City of Woburn, Massachusetts and encompasses three distinct properties consisting of the Aberjona, Whitney and Murphy properties. Brief descriptions of the ecological resources present within each of these three properties are provided below.

4.2.1.1 Habitat Characterization

The Aberjona property abuts the Aberjona River and associated wetlands to the northeast and northwest while developed areas are present to the southeast and southwest. There are four existing buildings on the property and a small parking area along Salem Street is also present. The remainder of the property is also highly disturbed and currently an open storage area and a canine recreation/exercise area.

The soils present within this property consist of fill material while vegetation cover is sparse and consists primarily of non-native plants. Due to the highly disturbed nature of this property, it does not provide significant habitat for ecological receptors. The adjacent wetlands that border on the Aberjona River were previously evaluated in the BERA conducted for the Aberjona River (EPA, 2004).

To the west of the Aberjona property is the Whitney property. Currently, several companies occupy a long rectangular building that still is present on the property, while other operations consisting primarily of firewood and landscaping businesses are evident over most of remaining portions of the property. The open areas around the building are heavily cluttered with brick, wood, and metal debris. A small forested/scrub-shrub wetland area and an intermittent stream are also present within the northern portion of this property while a seasonally ponded area is located immediately adjacent and south of the property. The primary wildlife habitat present on the Whitney property consists of the forested/scrub-shrub wetland community. This wetland is referred to as the Murphy Wetland and is discussed in greater detail below.

The Murphy property lies to the east of the B & M Railroad right-of-way and west of the Whitney property. An active waste oil handling and transfer facility and associated parking areas occupy most of the upland portion of the property although the foundation of a former building occupies the northern portion of the property. A chain-link fence is present around the periphery of the facility. Two buildings outside the fence are used for storage and office space. A wetland (Murphy Wetland) is present within the eastern and northern portions of this property and extends east on to the Whitney property.

With the exception of the Murphy Wetland that is present on both the Murphy and Whitney properties as well as the Wildwood property, no other significant habitat exists on the Site. The remaining portions of these parcels and the Aberjona property consist of occupied buildings, scrapped automobiles, wood/metal debris, and pavement/barren dirt areas. These non-significant habitat areas were not evaluated as part of this ERA. Hence, only the Murphy Wetland and its associated habitat was evaluated under this ERA.

The Murphy Wetland primarily present within the northwestern portion of the Site contains areas of forested/scrub-shrub wetland and a seasonally ponded area. The forested/scrub-shrub wetland areas are present within the southern and the eastern portions of the wetland while the seasonally ponded cover type is present within the western portion of the Murphy Wetland. The locations of these cover types are depicted in Figure 4-1. The seasonally ponded cover type extends over an area of approximately 0.8 acres while the forested/scrub-shrub wetland totals approximately 0.9 acres in extent.

Surface water within the seasonally ponded area was observed to range from several inches to several feet in depth in spring although no surface water was noted during the summer. During period of high water, overflow from the seasonally ponded area is discharged to a small intermittent stream. This stream flows to the east through the forested/scrub-shrub cover type and enters an 18-inch concrete pipe located beneath an existing unpaved road (the access road to the Wildwood Property that is located between the Whitney and Aberjona properties). Flow then continues to the east for approximately 400 feet where it is discharged to the Aberjona River.

Vegetation present within the seasonally ponded wetland cover type consists predominately of herbaceous species with tree and shrub vegetation present along the periphery of the ponded area as well as on some elevated mounded areas. The predominant herbaceous species present include purple loosestrife (*Lythrum salicaria*), common cat-tail (*Typha latifolia*), common reed (*Phragmites australis*), tussock sedge (*Carex stricta*) and duckweed (*Lemma* sp.). Woody vegetation present along the periphery of the seasonally flooded areas include cottonwood (*Populus deltoides*), red maple (*Acer rubrum*) and American elm (*Ulmus americana*) in the tree overstory with glossy-leaved buckthorn (*Rhamnus frangula*) and silky dogwood (*Cornus amomum*) present in the shrub understory.

Plant species noted in the forested/scrub-shrub wetland cover type include a tree overstory comprised primarily of cottonwood and red maple. The diameter at breast height (dbh) of the overstory trees ranges from 6 to 12 inches. Understory vegetation consists of glossy-leaved buckthorn, silky dogwood, common buckthorn (*Rhamnus cathartica*) in the shrub understory with poison ivy (*Toxicodendron radicans*), purple loosestrife, sensitive fern (*Onoclea sensibilis*) and soft rush (*Juncus effusus*) present within the ground layer.

4.2.1.2 Wildlife Receptor Species Characterization

A variety of wildlife receptors have either been observed at the Site or are expected to inhabit the various wetland cover types identified on the Site. As discussed above, the upland habitats have been extensively disturbed and do not currently provide significant habitat for ecological receptors. A list of potential amphibian, avian, mammalian and reptilian wildlife receptors noted or expected to utilize the identified wetland cover types is presented in Table 4-1. Brief discussions of wildlife receptors expected to be present within each habitat cover type are provided below.

The cover types identified within the Murphy Wetland consist of a seasonally ponded area (pond/shallow marsh/wet meadow) and forested/scrub-shrub wetland communities. These wetlands may support a variety of aquatic, semi-aquatic, and terrestrial species. These species would include invertebrates, amphibians, reptiles, birds and mammals. However, due to the

seasonal nature of the standing water, fish would not normally be expected to inhabit the Murphy Wetland.

Several amphibian and reptilian species may potentially use the aquatic habitats associated with the seasonally ponded area. Amphibians that may potentially use the seasonally ponded aquatic habitat as breeding or foraging habitat include the American toad (*Bufo americanus*), green frog (*Rana clamitans*) and northern leopard frog (*Rana pipiens*). Amphibians are generally insectivores consuming insects and other invertebrates although larger species such as the bullfrog (*Rana catesbeiana*) may also feed on small vertebrates. Several species of snakes and turtles are also expected this cover type. Snake species that may be present are generally carnivorous and include the northern water snake (*Nerodia sipedon*) and eastern ribbon snake (*Thamnophis sauritus*), two species that are often associated with aquatic/wetland habitats. Turtle species potentially present include the common snapping turtle (*Chelydra serpentina*) and eastern painted turtle (*Chrysemys picta*) are generally omnivorous species that forage on the water bottom.

The forested/scrub-shrub cover type would provide potential habitat for the more terrestrial amphibian and reptilian species that may only use the seasonally ponded area as a breeding area. These species include anurans such as the American toad and gray treefrog (*Hyla versicolor*) as well as snakes such as the northern brown snake (*Storeria dekayi*) and eastern garter snake (*Thamnophis sirtalis*).

A variety of avian species representing diverse feeding guilds may use the habitats provided by the Murphy Wetland. Aquatic bird species that may forage within the seasonally ponded area include waterfowl such as the mallard (*Anas platyrhynchos*) and wood duck (*Aix sponsa*). Several insectivorous bird species such as the tree swallow (*Tachycineata bicolor*) and eastern phoebe (*Sayornis phoebe*) are likely to hawk insects above the ponded area cover type as emerging insects are particularly abundant above an aquatic environment. Several omnivorous ground gleaners such as the red-winged blackbird (*Agelaius phoeniceus*) and song sparrow (*Melospiza melodia*) are also likely to nest and/or forage within this area after water levels recede in the summer or along its periphery during the spring and summer. Additional songbirds

are expected to inhabit the vegetation present along the periphery of the seasonally ponded area. These species would include shrub nesters such as the common yellowthroat (*Geothlypis trichas*) and tree nesters such as the yellow warbler (*Dendroica petechia*), insectivores that may consume terrestrial insects and recently emerged aquatic insects.

Birds noted within or likely to use the forested/scrub-shrub wetland cover type include various tree and shrub nesters/foragers. These species include insectivorous species such as the black-capped chickadee (*Parus atricapillus*), blue-winged warbler (*Vermivora pinus*), and downy woodpecker (*Picoides pubescens*). Other omnivorous species including the American robin (*Turdus migratorius*), gray catbird (*Dumatella carolinensis*) and northern cardinal (*Cardinalis cardinalis*) may also use this habitat for nesting and/or foraging.

Several mammal species representing different foraging guilds are expected to use the seasonally ponded cover type (see Table 4-1). Bats are likely to forage for insects above the ponded area as aquatic habitats are generally very productive sites for invertebrates including a variety of aquatic insects. Emerging insects would provide an important food resource for bats in the vicinity of the site. Species such as the little brown bat (*Myotis lucifugus*) and big brown bat (*Eptesicus fuscus*) are often associated with structures/ buildings located near aquatic habitats. Herbivorous mammals such as the muskrat (*Onodatra zibethicus*) and various small mammals may also forage on vegetation within the seasonally ponded area. The muskrat would primarily use this area during portions of the year when surface water is present while small mammals such as the white-footed mouse (*Peromyscus leucopus*) and meadow vole (*Microtus pennsylvanicus*) are only likely to be found within this cover type after surface water is absent. Mammalian predators such as the raccoon are expected to forage within or along the periphery of the ponded area. The raccoon is an omnivorous feeder that consumes a wide variety of items including macroinvertebrates and amphibians that may be associated with this habitat. The insectivorous short-tailed shrew (*Blarina brevicauda*) may also forage on insects and other invertebrates within this area during times when surface water levels are absent.

A diversity of small mammals including white-footed mice, short-tailed shrews, and red-backed voles (*Clethrionomys gapperi*) may inhabit the forested/scrub-shrub wetland cover type while

larger mammals including the Virginia opossum (*Diadelphis virginiana*) and white-tailed deer (*Odocoileus virginianus*) also forage within this habitat (see Table 4-1).

Based on available information from the Massachusetts Natural Heritage and Endangered Species Program (MANHESP, 2008), no listed rare species are known to inhabit the Site or immediate vicinity.

4.2.2 Hazard Identification

For the characterization of ecological risk, the primary media of concern at the Site are surface water, sediment and surface soils associated with the Murphy Wetland. Possible exposure pathways for ecological receptors present at the Site include the direct ingestion of contaminated surface water, sediment and/or surface soil and the indirect ingestion of contaminated biota in the food chain. Exposure of biota to subsurface soils and airborne contaminants (through volatization or fugitive dust emissions) via inhalation or dermal contact are not expected to represent as significant a pathway as direct ingestion of contaminated media or ingestion of contaminated biota in the food chain. Ecological receptors are also not anticipated to be directly exposed to groundwater contaminants although the evaluation of surface water and sediment within the Aberjona River BERA (EPA, 2004) indirectly evaluate contaminants transported through ground water discharge.

4.2.2.1 Data Management

Analytical data used in the risk assessment include recent surface water, sediment and surface soil sampling results from the Spring 2003 sampling as well as sediment and surface soil samples collected from the Site wetland in previous investigations. The following section describes which samples were grouped together for risk analysis. Summary statistics detailing contaminant concentrations (mean, 95 % UCL, and maximum) and frequency of detection for each media grouping are presented in Appendix C.

Environmental data used for the hazard identification were collected during several sampling events conducted by property owners, Settling Defendant, and split samples collected on behalf of EPA by TRC. The following discussion identifies the data deemed suitable for use in this ERA.

Background samples for sediment and surface water from wetland reference areas that were used by the Aberjona River BERA (EPA, 2004) as part of Operable Unit 3 (OU-3) were considered to be the most appropriate source of data to assess background conditions for the Murphy Wetland. Reference samples for surface water and sediment were collected as part of investigation activities conducted for OU-3 and were augmented by additional surface water and sediment reference samples collected in support of the Industri-Plex Superfund Site Investigation (EPA, 2005). Reference samples were collected from areas considered to be unaffected by OU-3 site activities and displaying no visual evidence of contamination. Analytical data for surface water and sediment wetland reference samples are presented in Appendix B.2. Wetland reference data were not used quantitatively in this ERA and do not impact the selection of COPECs (subsection 4.2.2.2).

As discussed previously, environmental data used in this risk assessment were collected during several sampling events. Detailed discussions of sampling approaches and the quality assurance and control activities implemented during the collection of the data, where available, are provided in the source documents. Data obtained as part of the Supplemental RI and associated TRC split data (RETEC 2003; TRC 2003) were validated according to EPA's Contract Laboratory Program (CLP) procedures and guidelines, as described in the Supplemental RI and the TRC Split Report, with one exception. Samples analyzed by the MassDEP VPH and EPH protocols were not validated because EPA validation protocols do not apply to these procedures. The respective analytical results are discussed in the Supplemental RI and the TRC Split Report.

Data obtained from the Clean Harbors 1998 Corrective Action Investigation Report (Part II) were not validated when published. EPA determined that within the limited circumstances of this project, validation of a representative subset of the analytical data may provide reasonable confidence in the quality of the data. EPA required that validation be conducted of a minimum

of 25 percent of the total samples analyzed using EPA Tier II protocols, and 5 percent of the samples using EPA Tier III protocols, in accordance with EPA Region I data validation guidelines.

The analytical data were summarized by environmental medium and grouped into exposure areas. For the ERA, the following media and exposure areas were selected for quantitative evaluation:

- Surface water at the Murphy Wetland;
- Sediment within the seasonally ponded portion of the Murphy Wetland; and,
- Surface soil within the forested/scrub-shrub portion of the Murphy Wetland.

The following sections summarize the environmental data available for use in the quantitative risk assessment for each of the exposure areas.

Surface water, sediment and surface soil samples were collected from the Murphy Wetland located between the upland portions of the Murphy, Whitney, Wildwood and Aberjona properties. Figure 4-1 depicts the location of surface water, sediment and surface soil samples used in the ERA. Analytical results of compounds detected in surface water, sediment and surface soil samples are presented in Appendix C. The locations and results of wetland sediment and surface soil samples collected and analyzed in 1995 and 1997 are presented in Clean Harbors, 1998. Results for samples collected and analyzed in 2002 by RETEC, and split with EPA, are presented in the Supplemental RI and in TRC's Split Report. For the purposes of this ERA, only surface water results from the 2002 sampling event are used quantitatively for the Murphy Wetland. The surface water samples collected by RETEC in 2002 are provided in Table 4-2.

The depth of sediment and surface soil generally considered for ecological exposure is 0 to 6 inches and 0 to 12 inches, respectively. The sediment and surface soil samples collected by RETEC in 2002 and split with EPA were from the 0 to 0.5 foot depth interval. The sediment and surface soil samples collected by Clean Harbors in 1995 and 1997 were collected from the 0 to 2

foot depth interval and were also used in the ERA. Three samples collected from 0 to 3 feet by RETEC in 1993 were not used in this ERA as most ecological exposure is expected to occur in the surficial sediments. Sediment and surface soil samples collected from the Murphy Wetland and used in the ERA are listed in Table 4-3 and Table 4-4, respectively. A summary of the analyses used in the ERA for each sediment and surface soil sample are also provided in Table 4-3 and Table 4-4, respectively.

Surface water, sediment and surface soil analytical results for the Murphy Wetland are summarized in Appendix C. The summary tables for chemicals detected in surface water, sediment and surface soil are also provided in Appendix C and include the frequency of detection, range of laboratory reporting limits for samples where compounds were not detected, mean concentration, 95% UCL, range of detected concentrations, and the location of maximum detected results.

4.2.2.2 Data Evaluation

Data were qualified by the analytical laboratory and validated as described previously. The qualification and validation of the analytical data, where performed, included a comparison of the site data to corresponding blank (laboratory, field, equipment, and trip) concentration data. Data rejected by the validation ("R" qualified) were not used. Estimated values (e.g., J qualified) were used in the risk assessment without modification. Analytical data from duplicate samples were combined as described in Section 2.0. Frequency of detection was calculated as the number of samples in which the chemical was detected over the total number of samples analyzed after the exclusion of rejected ("R" qualified) data. A duplicate sample was not considered a separate sample.

Since certain sediment samples were splits collected during the RETEC 2002 sampling event, more than one set of analytical results were available for some sampling locations. For these sampling locations, the multiple results were treated as unique samples rather than as duplicate samples (i.e., the multiple results were not averaged as duplicates). Therefore, in determining

the frequency of detection for split samples, the analytical results from the split samples were considered as separate values.

Analytical reporting limits for some sediment samples were elevated with respect to applicable ecological criteria or benchmarks. In order to reduce uncertainties associated with non-detected concentrations of analytes with high reporting limits, data for analytes with reporting limits that exceeded their applicable criterion or benchmark by a factor of two or greater (i.e., one-half the non-detect value would exceed the applicable benchmark) were not included in this ERA.

4.2.2.3 COPEC Selection

The selection of constituents of potential ecological concern (COPECs) for this ERA is based on a comparison of maximum detected contaminant concentrations from the media-specific Site environmental samples to conservative, media-specific, ecological criteria or benchmarks. Combining all data for a given medium results in a conservative list of COPECs for that medium. Constituents lacking ecological criteria or benchmarks were also retained as COPECs.

Surface Water

A total of three surface water samples were collected within the seasonally ponded area present within the Murphy Wetland in 2002. The locations of the surface water samples are depicted in Figure 4-1. Each of these samples was analyzed for total and dissolved metals (and total cyanide). A total of 13 inorganics were detected in one or more of the three samples. Screening benchmarks for these surface water samples were (in decreasing order of preference):

- National Recommended Water Quality Criteria (Freshwater – chronic) (EPA, 2009);
- EPA Region 5 RCRA Ecological Screening Levels (EPA, 2003a); and,
- EPA Region 3 BTAG Freshwater Screening Benchmarks (EPA, 2006a).

For metals with hardness-dependent screening benchmarks, the average detected water hardness value (127 mg/L) within the filtered surface water samples was used to calculate the benchmark.

The maximum concentrations detected in the surface water samples were compared to their applicable ecological screening benchmarks (Table 4-5). The maximum concentrations of four inorganics (aluminum, cyanide, iron, and manganese) were detected in unfiltered (total recoverable concentration) and/or filtered (i.e., dissolved) surface water samples above their respective benchmarks and subsequently retained as COPECs. The remaining nine detected inorganics (barium, calcium, chromium, cobalt, magnesium, nickel, potassium, sodium, and vanadium) have maximum concentrations less than their respective screening benchmarks. Therefore, these constituents were not retained as surface water COPECs.

Sediment

A total of 47 sediment samples were collected within the seasonally ponded area of the Murphy Wetland. The locations of the sediment samples are depicted in Figure 4-1. Over 60 analytes were detected in study area sediments, including a total of 7 VOCs, 23 SVOCs (including 16 PAHs), 5 pesticides (alpha and gamma chlordane and 4,4-DDT and its derivatives 4,4-DDD and 4,4-DDE), 2 PCB Aroclors, and 25 inorganics were detected in one or more of the sediment samples. Screening benchmarks for these sediment samples were (in decreasing order of preference):

- Consensus-Based Threshold Effect Concentrations (MacDonald et al., 2000);
- EPA Region 5 RCRA Ecological Screening Levels (EPA, 2003a);
- EPA Region III BTAG Freshwater Sediment Screening Benchmarks (EPA, 2006a); and,
- Threshold Effect Concentrations/Levels in Screening Quick Reference Tables (SQuiRTs) (Buchman, 2008); and
- Secondary Chronic Values via Equilibrium Partitioning (Jones et al., 1997).

The maximum concentration detected for each constituent was compared to sediment quality benchmarks (Table 4-6). Ecological sediment screening criteria were unavailable for several chemicals. In all cases, chemicals lacking screening criteria were included as COPECs in the ERA.

Although detected less frequently than other chemical classes, seven VOCs were detected in the sediment samples. Five VOCs were retained as COPECs. Acetone, 2-butanone and ethylbenzene were each detected at concentrations above their respective benchmarks while ethylene dibromide and methyl tert-butyl ether (MTBE) were also retained as COPECs because screening benchmarks are unavailable (Table 4-6).

Twenty-three SVOCs were detected in the Murphy Wetland sediments. The detection percentage for many of the PAHs was greater than 60%. Locations of maximum detections varied, but a number of maximum levels were found in samples collected within the seasonally ponded area at sample MR-12. SVOCs detected at levels exceeding screening benchmarks included 2-methylnaphthalene, 2-methylphenol, acenaphthene, acenaphthylene, anthracene, benzo(a)anthracene, benzo(a)pyrene, benzo(g,h,i)perylene, benzo(k)fluoranthene, bis(2-ethylhexyl)phthalate, chrysene, dibenz(a,h)anthracene, fluoranthene, fluorene, indeno(1,2,3-cd)pyrene, phenanthrene, phenol and pyrene. These compounds were selected as COPECs. No screening benchmarks were available for acetophenone, benzaldehyde, or carbazole. These contaminants were also retained as COPECs.

Five pesticides, two PCB Aroclors and 12 dioxin-like PCB congeners were also detected in the Murphy Wetland sediments. Pesticides and PCB Aroclors with maximum detected levels exceeding screening benchmarks included 4,4'-DDD, 4,4'-DDE, 4,4'-DDT, *alpha*-chlordane, *gamma*-chlordane, and Aroclors 1254 and 1260. These compounds were selected as COPECs. There were no criteria available for the dioxin-like PCB congeners. These congeners were also retained as COPECs.

A total of 25 inorganics were detected in site-related sediments, with the majority (15) detected in 100% of the samples. Maximum levels of all analytes except aluminum, cobalt, manganese, selenium and silver exceeded their respective screening benchmarks or screening benchmarks are unavailable.

Surface Soil

A total of 18 surface soil samples were collected from the forested/scrub-shrub areas within the Murphy Wetland. The locations of the surface soil samples are depicted in Figure 4-1. Constituents detected in the surface soil samples were limited to inorganics and PCB Aroclors. A total of 24 inorganics were detected in surface soil samples while three PCB Aroclors (1248, 1254 and 1260) were detected.

A comparison of the maximum detected concentrations for each constituent with their respective surface soil screening benchmarks is presented in Table 4-7. Screening benchmarks for these surface soil samples were (in decreasing order of preference):

- EPA Ecological Soil Screening Levels (eco-SSLs). The lowest reported concentration for plants, invertebrates, birds and mammals was selected. (EPA, 2003b and c; 2005b through h; 2006b; 2007a through e; 2008a);
- EPA Region 5 RCRA Ecological Screening Levels for Soil (EPA, 2003a); and,
- Toxicological Benchmarks in Screening Quick Reference Tables (SQuiRTs) (Buchman, 2008).

A total of nine inorganics and PCB Aroclors 1248 and 1254 were detected at concentrations above their screening benchmarks and were retained as COPECs. An additional four inorganics were retained as COPECs as screening benchmarks are unavailable for calcium, magnesium, potassium and sodium. Eleven inorganics were eliminated as COPECs since the maximum concentrations of these constituents were detected at levels below their screening benchmarks. Aluminum and iron were not included as COPECs as these metals are of ecological concern if soil pH is less than 5.5 and 5.0, respectively. Previous soil sampling on the Murphy property (RETEC, 2003) for soil pH at 9 samples (varying depths from 0 to 2 feet to 0 to 10 feet) reported only 1 sample with a soil pH less than 5.5 (pH was 5.2). The average pH of these samples was 5.96.

4.2.2.4 Ecotoxicity Literature Review

An ecotoxicity literature review has been performed for selected COPECs and is discussed in the following subsections.

Volatile Organic Compounds (VOCs)

In general, as a group, VOCs are not acutely toxic to most aquatic ecological receptors at very low concentrations. VOCs were detected in several sediment samples collected at the Murphy Wetland. VOCs were not analyzed in the three surface water samples. VOCs are often not found within surficial sediment and surface water due to their tendency to volatilize into the air. At high concentrations, VOCs in surface water and sediment may impact aquatic receptors. These volatile compounds, when present at high concentrations, may also present an inhalation hazard to animals that inhabit confined areas (*e.g.*, burrows or lodges). VOCs do not bioaccumulate to any significant degree, and therefore, do not generally pose a risk to environmental receptors via trophic transfer.

Semi-Volatile Organic Compounds (SVOCs)/

Phthalates. Aquatic life toxicity data indicate that bis(2-ethylhexyl) phthalate (BEHP) is not toxic to aquatic organisms at or below its solubility limit. The solubility of BEHP in water is low with a value of approximately 300 µg/L reported. Due to its high organic carbon/water partition coefficient, BEHP is expected to adsorb to organic and inorganic particulate materials and have limited bioavailability to sediment biota. Therefore, sediment concentrations of BEHP that may result in toxic effects to benthic organisms are very unlikely under natural conditions (Jones et al., 1997).

Significant adverse effects on mice reproduction were noted at diets containing 1000 mg bis(2-ethylhexyl)phthalate (BEHP)/kg during a 105-day study period. Diets containing 100 mg BEHP/kg did not result in adverse reproductive effects to mice (Sample et al., 1996). A four-week study involving feeding ringed doves a diet containing 100 mg BEHP/kg did not observe adverse affects regarding reproduction (Sample et al., 1996).

Polyaromatic Hydrocarbons (PAHs). In aquatic environments, PAHs rapidly become adsorbed to organic and inorganic particulate materials and are deposited in sediments (Neff, 1985). Once adsorbed to sediment, PAHs have limited bioavailability to aquatic organisms (Neff, 1985). However, PAHs deposited in sediments can be toxic to benthic invertebrates. In sediment toxicity tests with the tubificid, *Limnodrilus hoffmeisteri*, Lotufo and Fleeger (1996) observed a median lethal phenanthrene level of 298 mg/kg (sediment organic carbon content = 0.7%). In the same study, pyrene levels up to 841 mg/kg were not acutely toxic. Decreases in tubificid reproduction were observed at much lower levels (IC_{25} s [concentration associated with a 25% inhibition in measured endpoint relative to control] of 40.5 mg/kg and 59.1 mg/kg for phenanthrene and pyrene, respectively).

Sediment-associated PAHs can be accumulated by bottom-dwelling invertebrates and fish (Eisler, 1987a). Great Lakes sediments contaminated with elevated levels of PAHs were reported by Eadie *et al.* (1983 *cited in* Eisler, 1987a) to be the source of body burdens in bottom-dwelling invertebrates. Lake *et al.* (1985 *cited in* Eisler, 1987a) found that marine mussels (*Mytilus edulis*) and annelids (*Nereis virens*), exposed for 28 days to sediments heavily contaminated with PAHs, accumulated up to 1,000 times more than controls.

In aquatic environments, exposure to ultraviolet light can result in photomodification of some PAHs to products with increased polarity, water solubility, and toxicity compared to the parent compound (Duxbury *et al.*, 1997). Ireland *et al.* (1996) showed that the photoinduced toxicity of PAHs to the daphnid, *Ceriodaphnia dubia*, occurred frequently during low-flow conditions and wet weather runoff, and was reduced in turbid conditions. In studies on the marine amphipod, *Rhepoxynius abronius*, ultraviolet radiation exposure enhanced the toxicity of fluoranthene and pyrene in sediments, but did not affect the toxicity of acenaphthene and phenanthrene (Swartz *et al.*, 1997). Pelletier *et al.* (1997) found that the phototoxicity of individual PAHs (anthracene, fluoranthene, pyrene) to marine bivalves *(Mulinia lateralis)* and marine shrimp *(Mysidopsis bahia*) were 12 to >50,000 times that of conventional toxicity.

The capacity to metabolize PAHs varies among organisms. Varanasi *et al.* (1985 *cited in* ATSDR, 1995) ranked the extent of benzo(a)pyrene metabolism by aquatic organisms as follows: fish > shrimp > amphipod > crustaceans > mussels. The fact that mussels are ranked last may be because mussels show no or limited mixed function oxidase (MFO) activity. MFO is an enzyme system responsible for the initiation of metabolism of various lipophilic organic compounds, including PAHs (Neff, 1985).

The primary effect of PAH exposure in mammalian laboratory species is tumor development (Eisler, 1987a). EPA has classified benzo(a)anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene, benzo(a)pyrene, dibenz(a,h)anthracene, chrysene, and indeno(1,2,3-cd)pyrene as carcinogens (ATSDR, 1995). Acenaphthylene, anthracene, benzo(g,h,i)perylene, fluoranthene, fluorene, phenanthrene and pyrene are not classified as carcinogens by EPA (ATSDR, 1995).

Pesticides/Polychlorinated Biphenyls (PCBs)

DDD, DDE, and DDT. LC_{50} values between 0.2 and 1,230 µg/L have been reported for aquatic invertebrates exposed to DDT and its breakdown products, DDD and DDE (EPA, 1980). Other 96-hr LC_{50}s, reported in Mayer and Ellersieck (1986), include 1 µg/L for the freshwater amphipod, *Gammarus lacustris*, and 4 µg/L for the isopod, *Asellus brevicaudus*, as well as 70, 10 and 7 µg/L for mosquito larvae (*Culex fatigans* and *Anopheles albimanus*) and stonefly (*Pteronarcys californi*a), respectively. The most sensitive freshwater invertebrate reported by Mayer and Ellersieck (1986) was the water flea, *D. pulex*, with a 48-hr EC_{50} of 0.36 µg/L, based on immobilization.

In water, DDT is absorbed by fish directly through the skin, and is also accumulated by invertebrates, which are prey for many fish species. A range of LC_{50} values from 2 to 21 µg/L are given for freshwater fish in Connell and Miller (1984). LC_{50} values for freshwater fish species are also presented in Mayer and Ellersieck (1986). The most sensitive species reported was largemouth bass (*Micropterus salmoides*), with a 96-hr LC_{50} of 1.5 µg/L. Other LC_{50}s reported by Mayer and Ellersieck (1986) were 4.9, 5.0 and 15 µg/L for bluegill sunfish (*L.*

macrochirus), black bullhead (*Ictalurus melas*), and channel catfish (*Ictalurus punctatus*), respectively. Chronic effects have been observed at 0.74 µg/L in chronic life-cycle tests with fathead minnows (*P. promelas*) (EPA, 1980).

Sediment ERLs for DDT, DDD, DDE and total DDT are 1, 2, 2.2, and 1.58 µg/kg, respectively (Long and Morgan, 1990; Long *et al.*, 1995). Effects Range-Median (ERM) values for these same compounds are 7, 20, 27, and 46.1 µg/kg, respectively (Long and Morgan, 1990; Long *et al.*,1995).

Median lethal dietary concentrations in the range of 651 to 1,160 mg/kg have been reported for northern short-tailed shrews (*Blarina brevicauda*) exposed to DDT for up to 17 days via a corn oil diet (Blus, 1978). In studies reported in Klaassen *et al.* (1996), female rats given single DDT doses of 50 mg/kg showed estrogenic effects. Also reported, an LD_{50} of 113 mg/kg for male rats fed DDT, and an LD_{50} of 880 mg/kg for rats fed DDE. At sufficiently high doses, DDT can induce death in organisms by interfering with central nervous system transmission through the disruption of sodium ion passage (Connell and Miller, 1984).

Acute median lethal dosages for birds include LD_{50}s of >2,240 mg/kg for mallard ducks and 841 mg/kg for Japanese quail (Hudson *et al.*, 1984). Following chronic exposures to DDT dietary concentrations of 100 mg/kg, 50% of exposed adult mallards died in about one year. DDE has been found to cause eggshell thinning in birds consuming a diet containing DDT and its breakdown products. Weimeyer *et al.*, (1970) found 14 to 15% eggshell thinning in American kestrels (*Falco sparverius*) given a daily DDE dietary concentration of 3 mg/kg for less than 7 months. Stendell *et al.* (1989) fed pine voles (*Microtus pinetorum*) from pesticide-contaminated apple orchards to three captive American kestrels. The pine voles contained 48 mg/kg DDE, 3.5 mg/kg DDD, and 14.1 mg/kg DDT. One of the kestrels, which died at 31 days, contained 147 mg/kg DDE in the carcass (wet weight).

Chlordane (*alpha* and *gamma*). Chlordane was formerly used as a pesticide in the United States. It is very persistent in the environment and bioaccumulates in aquatic and terrestrial organisms (EPA, 1985). Aquatic LCVs for chlordane include 1.6, 16, and 1.09 µg/L for fish,

daphnids, and non-daphnid invertebrates, respectively (Suter and Tsao, 1996). EqP-based sediment LCVs, based on 1% sediment organic carbon content, were calculated at 26,000, 260,000, and 18,000 µg/kg for fish, daphnids, and non-daphnid invertebrates, respectively (Jones *et al.*, 1997).

Polychlorinated Biphenyls. PCBs have been shown to cause reproductive failure, birth defects, skin lesions, tumors, liver disorders, and death in fish and wildlife (Eisler, 1986a). Due to their high lipid solubility, PCBs bioaccumulate and biomagnify within the food chain. At the study area, the maximum detected concentrations of two PCB Aroclors, Aroclor-1254 and Aroclor-1260, were greater than screening criteria.

Eisler (1986a) reports LC_{50} values for freshwater and marine organism exposed to various Aroclors from 0.1 to 10 µg/L, with crustaceans and younger developmental stages being the most sensitive. For Aroclor-1260, the LCV for fish is <1.3 µg/L (Suter and Tsao, 1996). Based on the EqP approach and 1% sediment organic carbon content, the LCV for fish exposed to Aroclor-1260 in sediment is <63,000 µg/L (Jones *et al.*, 1997).

Fish are a major source of PCBs to wildlife (O'Hara and Rice, 1996). Mink, which consume fish, have been found to be very sensitive to PCBs (Fuller and Hobson, 1986 *cited in* O'Hara and Rice, 1996). A LOAEL for reproductive effects of 3.425 mg/kg-day was observed in mink exposed to Aroclor-1016 in the diet for 18 months (Aulerich and Ringer, 1980 *cited in* Sample *et al.*, 1996). As in mammals, PCBs can severely affect the reproduction of avian piscivores (O'Hara and Rice, 1996).

Waterfowl may also be impacted by PCB contamination. In a study by Heath *et al.* (1972 *cited in* Eisler, 1986a), LD_{50}s for mallards fed Aroclor-1248 and Aroclor-1260 were associated with dietary concentrations of 2,798 mg/kg and 1,975 mg/kg, respectively.

Inorganics

Aluminum. The LCV for fish is 3,288 µg/L based on 28-day embryo-larval tests with the fathead minnow, *P. promelas* (EPA, 1988 *cited in* Suter and Tsao, 1996). Lowest chronic value for daphnids was reported as 1,900 µg/L (McCauley *et al.*, 1986 *cited in* Suter and Tsao, 1996). An aluminum BCF of 268 has been reported for brook trout (*Salvelinus fontinalis*) and BCFs for water fleas (*D. magna*) exposed to aluminum chloride ranged from 320 to 1,020 (Cleveland *et al.*, 1991; Havas, 1985 *cited in* AQUIRE [EPA, 1998b]).

Antimony. Antimony (Sb) is a naturally occurring metal that is used in various manufacturing processes. LCVs for antimony exposure to fathead minnow, *P. promelas*, and daphnid, *D. magna*, of 1,600 and 5,400 Φg/L, respectively, were reported by Kimball (no date *cited in* Suter and Tsao, 1996). For freshwater algae (*Selenastrum capricornutum*), inhibition of the synthesis of chlorophyll a was observed during antimony exposure of 610 Φg/L (96-hour EC_{50}) (EPA, 1978 *cited in* Suter and Tsao, 1996). Accumulation of antimony has been demonstrated in marine invertebrates (Amiard, 1973 *cited in* AQUIRE [EPA, 1998b]).

Antimony can be toxic to mammals. Testing by Schroeder *et al.* (1968 *cited in* Sample *et al.*, 1996) showed a chronic oral dose of 5 mg/L in drinking water caused a reduction in the median life span of female mice.

Arsenic. The toxicity of arsenic depends on its form: trivalent arsenic [As (III)] leads to enzyme inhibition, while pentavalent arsenic [As (V)] probably acts by interfering with formation of ATP (uncoupling of oxidative phosphorylation) (Eisler, 1988a). Arsenic has been found to be carcinogenic, teratogenic, embryotoxic, and fetotoxic in laboratory species (NAS, 1980).

Reported LC_{50}s for freshwater invertebrates vary widely. Several of the values in this range include: a 96-hour As (V) LC_{50} for *D. magna* of 7,400 µg/L (EPA, 1980 *cited in* Eisler,1988a); a 96-hour As (III) LC_{50} for *D. pulex* of 1,300 µg/L (EPA, 1980 *cited in* Eisler, 1988a); a 96-hour As (III) LC_{50} for *Pteronarcys californica* of 38,000 µg/L (Johnson and Finley, 1980 *cited in* Eisler, 1988a); and a 96-hour As (III) LC_{50} for *Simocephalus serrulatus* of 810 µg/L (EPA, 1985 *cited in* Eisler, 1988a).

Eisler (1988a) reports that BCFs for arsenic in aquatic invertebrates and fish are relatively low. BCF values for As (III) in most aquatic invertebrates and fish were not greater than 17. For As (V), the BCFs were not greater than 6, and the maximum BCF for organoarsenicals was 9 (EPA, 1980; EPA, 1985 *cited in* Eisler, 1988a).

Sediment ERL and ERM values for arsenic are 8.2 and 70 mg/kg, respectively (Long *et al.*, 1995). The Ontario Ministry of the Environment and Energy (OMEE) Lowest Effect Level (LEL) and Severe Effect Level (SEL) for arsenic are similar, at 6 and 33 mg/kg, respectively (Persaud *et al.*, 1993).

Toxicity to terrestrial receptors may vary greatly depending on the form of arsenic. A single oral dose of 1 to 4 grams of sodium arsenite was lethal to cattle (*Bos* spp.) (NRCC, 1978 *cited in* Eisler, 1988a). A single oral dose of 2.5 to 7.5 mg/kg of arsenic acid was also acutely toxic to domestic goats, *Capra* spp. (NRCC, 1978 *cited in* Eisler, 1988a). A 50 to 150 mg dose of sodium arsenite was lethal to a domestic dog, *Canis familiaris* (NRCC, 1978 *cited in* Eisler, 1988a), and single oral doses of 39.4 and 15.1 mg/kg of arsenic trioxide were associated with 96-hour LD_{50}s in mice, *Mus* sp. and rats, *Rattus* sp., respectively (NAS, 1977 *cited in* Eisler, 1988a).

Toxicity benchmarks for avian species, based on exposure to sodium arsenite, include: an acute oral LD_{50} of 47.6 mg/kg for California quail, *Callipepla californica* (Hudson *et al.*, 1984); an acute oral LD_{50} of 323 mg/kg for mallard, *Anas platyrhynchos* (Hudson *et al.*, 1984); and an acute oral LD_{50} of 389 mg/kg for ring-necked pheasant, *Phasianus colchicus*, (Hudson *et al.*, 1984). A No Observable Adverse Effect Level (NOAEL) of 1.25 mg/kg-day was estimated in chickens after 56 days of exposure (Hermayer *et al.*, 1977 *cited in* NAS, 1980).

Barium. Barium readily forms insoluble carbonate and sulfate salts which have low toxicity, but soluble barium salts may be toxic (EPA, 1985). The Tier II SCV calculated by Suter and Tsao (1996) is 4.0 µg/L. In seawater, barium concentrations ranging from 0.1 to 0.9 mg/L have been shown to be toxic to mussel embryos (*Mytilus californianus*) (Spangenberg and Cherr, 1996).

BCFs for barium in marine animals, plankton and brown algae are 100, 120 and 260, respectively (ATSDR, 1992). Although there is some evidence that barium may bioconcentrate in certain terrestrial plants and aquatic freshwater organisms, the extent of plant uptake and the subsequent uptake by aquatic or terrestrial animals is not known (ATSDR, 1992). Estimated soil-to-plant bioaccumulation factors (BAFs) are 0.015 to 0.15 (Bysshe, 1988).

Guidelines for the pollution classification of Great Lakes harbor sediments classify sediment barium concentrations of <20, 20-60, and >60 mg/kg as non-polluted, moderately polluted, and heavily polluted, respectively (EPA, 1977 *cited in* Beyer, 1990).

Oral LD_{50}s for barium (as barium carbonate) are reported as 418 and 200 mg/kg for rats and mice, respectively (Sax and Lewis, 1989). Exposure of barium chloride to rats via water consumption over a 16-month period resulted in a NOAEL of 5.1 mg/kg-day for effects on growth and hypertension (Perry *et al.,* 1983 *cited in* Sample *et al.,* 1996).

Beryllium. LCVs for freshwater daphnids and plants are 5.3 and 100,000 Φg/L, respectively (Suter and Tsao, 1996). Bluegill sunfish have been shown to bioconcentrate beryllium (Barrows *et al.,* 1980 *cited in* AQUIRE [EPA, 1998b]). A NOAEL for longevity and weight loss in rats of 0.66 mg/kg-d was observed by Schroeder and Mitchner (1975 *cited in* Sample *et al.,* 1996) in a study where rats were exposed to beryllium sulfate in drinking water over their lifetime.

Cadmium. The literature review of cadmium effects by Eisler (1985) concluded that freshwater organisms were the most sensitive biota. Concentrations of 0.8 to 9.9 µg/L in water were lethal to several species of aquatic insects, crustaceans, and teleosts. Eisler (1985) also reported that cadmium concentrations ranging from 0.7 to 5.0 µg/L were associated with sublethal effects (decreased growth, inhibited reproduction, and population alterations) in these same groups. Cadmium has also been shown to be highly toxic to South African clawed frog (*Xenopus laevis*) embryos (Herkovits *et al.,* 1997). At the most sensitive embryonic stage, a concentration of 1 mg Cd (II)/L arrested development in 100% of exposed individuals.

Mammals and birds are less sensitive to the biocidal properties of cadmium than freshwater biota (Eisler, 2000). Cadmium in mammals can bioaccumulate and interfere with zinc-containing enzymes, resulting in impairment of kidney function, reproduction, and growth (Scheuhammer, 1987).

Chromium. Chromium has not been observed to biomagnify, and concentrations are usually highest at lower trophic levels (Eisler, 1986b). The toxicity of chromium varies widely between organisms and is dependent on form. Adverse effects of chromium to sensitive freshwater species have been documented at 10 µg/L of Cr (VI) and 30 µg/L of Cr (III) (Eisler, 1986b). For wildlife, adverse effects have been reported at 5.1 mg and 10.0 mg of Cr (VI) and Cr (III), respectively, per kilogram of diet (Eisler, 1986b). These data support the generalization drawn by Eisler that Cr (VI) is more toxic to freshwater species and mammals than Cr (III).

Exposure to Cr (VI) has been demonstrated to reduce growth rates in both freshwater algae and duckweed, and to affect the survival and fecundity of cladocerans (Eisler, 1986b). Some salts of chromium are carcinogenic in rats and Cr (VI) is a teratogen in hamsters (EPA, 1985).

Cobalt. Cobalt is an essential element that can be accumulated by plants and animals (EPA, 1985). Mobility in aquatic systems is limited because cobalt adsorbs to clay minerals and hydrous oxides of iron, manganese, and aluminum in the clay fractions of sediments and soils (EPA, 1985). The LCV for daphnids is 5.1 µg/L (Suter and Tsao, 1996). Estimated soil-to-plant BAFs range from 0.007 to 0.02 (Bysshe, 1988).

Copper. Mean acute toxicity values for freshwater species range from 7.2 µg/L for the daphnid, *D. pulicaria*, to 10,200 µg/L for bluegill sunfish, *L. macrochirus* (EPA, 1985). Chronic toxicity values for freshwater species range from 3.9 µg/L for brook trout to 60.4 µg/L for northern pike (EPA, 1985).

Earthworms bioconcentrate copper and can be negatively affected via a decrease in growth, reproduction, or survival (Beyer, 1990). For the soil-dwelling collembolan, *Folsomia fimetaria*, Scotts-Fordsmand *et al.* (1997) reported a soil EC_{10} for reproduction of 38 mg/kg, and a soil

EC_{10} between 509 and 845 mg/kg for growth (depending on sex and developmental stage). Bysshe (1988) suggested that concentrations of copper in soils will generally kill plants before they can accumulate tissue concentrations that are toxic to grazing animals. However, experimentation has shown that chronic exposure to dietary copper can impact both sheep and swine (EPA, 1985). Aulerich *et al.* (1982 *cited in* Sample *et al.*, 1996) determined a NOAEL for reproductive effects in mink of 11.7 mg/kg-day.

Cyanide. Cyanide most commonly occurs as hydrogen cyanide and its salts--sodium and potassium cyanide. Cyanides are both man-made and naturally occurring substances. They are found in several plant species as cyanogenic glycosides and are produced by certain bacteria, fungi, and algae. In very small amounts, cyanide is a necessary requirement in the human diet. Cyanides are released to the environment from industrial sources and are not known to biomagnify in organisms (Eisler, 1991).

Fish were the most sensitive aquatic organisms to cyanide as adverse effects on swimming and reproduction were reported between 5 and 7.2 ug/L with lethal effects noted between 20 and 76 ug/L (Eisler, 1991). The acute and chronic ambient water quality criteria are 22 and 5.2 ug/L, respectively (EPA, 2009).

Cyanides are readily absorbed orally. The central nervous system (CNS) is the primary target organ for cyanide toxicity. Neurotoxicity has been observed in animals following ingestion and inhalation of cyanides. Cardiac and respiratory effects, possibly CNS-mediated, have also been reported. Short-term exposure to high concentrations produces almost immediate collapse, respiratory arrest, and death (Hartung, 1982; EPA, 1985). In animal studies, cyanides have produced fetotoxicity and teratogenic effects.

No adverse effects were observed on reproductive performance or lactation of rats fed 500 mg cyanide/kg diet throughout gestation and lactation. Litter size, weight of pups at birth, and food consumption and growth rate of pups were not significantly different from controls (Tewe and Maner, 1981).

Iron. The NAWQC for iron is 1,000 µg/L. The LCV for fish is 1,300 µg/L (Amelung, 1981 *cited in* Suter and Tsao, 1996). This concentration caused 100% morality in an embryo-larval

test with rainbow trout exposed to dissolved iron salts. The LCV for daphnids (158 µg/L) is a threshold for reproductive effects from a 21-day test of iron chloride with *D. magna* (Dave, 1984 *cited in* Suter and Tsao, 1996). Pentreath (1973 *cited in* AQUIRE [EPA, 1998b]) measured an iron BCF of 9.53 for the mussel, *Mytilus edulis*.

Lead. Lead is toxic to all phyla of aquatic biota (Wong *et al.*, 1978 *cited in* Eisler, 1988b). Based on a review of toxicity testing literature, Eisler (1988b) reported adverse effects to aquatic biota associated with lead concentrations ranging from 1 to 5.1 µg/L.

For domestic and laboratory animals, Eisler (1988b) reported that survival was reduced at acute oral doses of 5 mg/kg (rat), at chronic oral doses of 5 mg/kg-day (dog), and at dietary doses of 1.7 mg/kg-day (horse). Lead affects the kidneys, bone and central nervous system in mammals and can have adverse effects on histopathology, neuropsychology, fetotoxicity, growth and reproduction (Eisler, 2000). In addition, lead may interfere with enzymes involved in cellular oxidative processes, and possibly affect the release of impulses at certain nerve endings (Locke and Thomas, 1996). The primary source of lead poisoning in wild waterfowl, and in large raptors that prey on waterfowl, has been the ingestion of shotgun pellets (Locke and Thomas, 1996).

Adverse effects associated with lead in soil have been documented for terrestrial plants (Bysshe, 1988; Eisler, 1988b). Earthworms may bioaccumulate lead (Beyer, 1990; Roberts and Dorough, 1985), and high concentrations of lead may be toxic to earthworms, affecting both survival and rate of reproduction. Eisler (1988b) generalized that organolead compounds are more toxic than inorganic lead compounds, and that younger organisms are more susceptible than older organisms.

Mercury. Mercury is a mutagen, teratogen, and carcinogen, and causes embryocidal, cytochemical, and histopathological effects. Methylmercury can be bioconcentrated in organisms and biomagnified through food chains (Wolfe *et al.*, 1998; Eisler, 1987b).

Chronic values for inorganic (or total) mercury are <0.23 µg/L for fish (*P. promelas* through the embryo-larval stage) and 0.96 µg/L for daphnids (*D. magna* in flow-through life-cycle tests) (Call *et al.,* 1983; Biesinger *et al.,* 1982, respectively, *cited in* Suter and Tsao, 1996). The transformation of inorganic mercury by anaerobic sediment microorganisms produces methylmercury (Wolfe *et al.,* 1998). Chronic values for methylmercury are reported as 0.52 µg/L for fish (brook trout in three-generation life-cycle test) and <0.04 µg/L for daphnids (McKim *et al.,* 1976; Biesinger *et al.,* 1982, respectively, *cited in* Suter and Tsao, 1996).

As summarized in Sample *et al.* (1996), reproductive NOAELs for animals exposed to mercury in their diet include 1 mg/kg-day for mink exposed to mercuric chloride for 6 months (Aulerich *et al.,* 1974 cited in Sample *et al.,* 1996), 0.45 mg/kg-day for Japanese quail exposed to mercuric chloride for 1 year (Hill and Schaffner, 1976 cited in Sample *et al.,* 1996), 13.2 mg/kg-day for mice exposed to mercuric sulfide for 20 months (Revis *et al.,* 1989 cited in Sample *et al.,* 1996), and 0.032 mg/kg-day for rats exposed to methyl mercury chloride over 3 generations (Verschuuren *et al.,* 1976 cited in Sample *et al.,* 1996).

Nickel. LCVs for daphnids, non-daphnid invertebrates, and aquatic plants are <5, 128.4, and 5 µg/L, respectively (Suter and Tsao, 1996). Nickel is not significantly accumulated by aquatic organisms (EPA, 1985). Bysshe (1988) estimated a soil-to-plant BAF of 0.06 for nickel.

Rats fed 40 mg/kg-day of nickel sulfate hexahydrate in their food over 3 generations showed no effects on reproduction (Ambrose *et al.,* 1976 *cited in* Sample *et al.,* 1996). The NOAEL for mallards orally exposed to nickel sulfate for 90 days was 77.4 mg/kg-day (Cain and Pafford, 1981 *cited in* Sample *et al.,* 1996).

Selenium. In flow-through toxicity studies, selenium, as selenate, was found to reduce larval fathead minnow biomass at 108.1 µg/L (LOEC) and to impair algal and rotifer population growth rates at similar concentrations (Dobbs *et al.,* 1996). As reported in Suter and Tsao (1996), LCVs for fish, daphnids, and aquatic plants are 88.32, 91.65 and 100 µg/L, respectively.

Regardless of the original source, adverse environmental effects appear to result largely from transfer of selenium from lower to higher trophic levels (Riedel and Sanders, 1996). High bioconcentration and accumulation of selenium from water by numerous species of algae, fish, and invertebrates is well documented at levels of 0.015 to 3.3 µg/kg (Eisler, 1987c). Game fish populations have suffered reproductive failure after bioaccumulation of selenium from concentrations of about 10 µg/L dissolved selenium (Cumbie and Van Horne, 1978 *cited in* Riedel and Sanders, 1996). Mortality, gross malformations, and internal abnormalities of the young of several wetland bird species have been observed where high selenate concentrations exist (up to 350 µg/L) (Ohlendorf *et al.,* 1986; Ohlendorf *et al.,* 1990 *cited in* Riedel and Sanders, 1996). In mammals, selenium is an essential trace element that shows evidence of toxicity at higher doses (Domingo, 1994).

Based on biological effects data compiled from the literature, sediment selenium concentrations of 2.5 mg/kg would be a threshold based on predicted effects, and concentrations of 4.0 mg/kg would be the observed threshold for fish and wildlife toxicity (Van Derveer and Canton, 1997).

Thallium. Information on the toxicity and biological fate of thallium is limited. LCVs for fish, daphnids, and plants are 57, 130, and 100 µg/L, respectively (Suter and Tsao, 1996). The reproductive subchronic LOAEL for male rats orally exposed to thallium sulfate in drinking water for 60 days was 0.74 mg/kg-day (Formigli *et al.,* 1986 *cited in* Sample *et al.,* 1996). Thallium has been demonstrated to bioconcentrate in duckweed (*Lemna minor*) (Kwan and Smith, 1991; Kwan and Smith, 1988 *cited in* AQUIRE [EPA, 1998b]).

Vanadium. Information on the toxicity and biological fate of vanadium is limited. Suter and Tsao (1996) report LCVs of 80 µg/L for fish and 1,900 µg/L for daphnids. In a study conducted with mallard ducks, individuals were exposed to vanadyl sulfate in their diet for 12 weeks. The NOAEL for mortality, body weight, and blood chemistry was 11.38 mg/kg-day (White and Dieter, 1978 *cited in* Sample *et al.,* 1996).

Zinc. Adverse effects of zinc exposure have been documented on the growth, reproduction, and survival of freshwater species of aquatic plants, invertebrates, and vertebrates at concentrations

between 10 and 25 µg/L (Eisler, 1993). 96-Hour LC_{50} values for freshwater invertebrates range from 32 to 40,930 µg/L and from 66 to 40,900 µg/L for freshwater teleosts (Eisler, 1993). LCVs for fish, daphnids, non-daphnid invertebrates, and aquatic plants are 36.41, 46.73, >5,243, and 30 µg/L, respectively (Suter and Tsao, 1996). BCF values ranged from 107 to 1,130 for insects and from 51 to 432 for freshwater fish (EPA, 1980 *cited in* Eisler, 1993).

Varying concentrations of zinc may also affect sediment invertebrates. At a mine tailings site, populations of freshwater oligochaetes and leeches were reduced in numbers of individuals and numbers of taxa in areas where the concentration of zinc in sediment was >20 g/kg (Willis, 1985 *cited in* Eisler, 1993). In contrast, the NOAA ERL value for sediment, which reflects a level at which impacts are possible, is 150 mg/kg (Long *et al.*, 1995).

Reduced survival has been reported for terrestrial plants (sensitive species) and soil invertebrates at soil concentrations of >100 mg/kg and from 470 to 6,400 mg/kg, respectively (Eisler, 1993). Increased dietary zinc has also been shown to have adverse effects on poultry, avian wildlife, livestock and laboratory animals (Eisler, 1993).

4.2.3 Site Conceptual Model

As discussed above in Section 4.2.1, a variety of ecological receptors may be present within the Murphy Wetland present at the Site. Insects and other invertebrates, amphibians, reptiles, birds and mammals representing a diverse assemblage of feeding guilds are important components of the ecological community present within the Murphy Wetland. These species may potentially be exposed to surface water, sediment and surface soil present at the site and forms the basis to the development of a site conceptual model.

4.2.3.1 Exposure Pathways

The former activities at the site may have resulted in contamination on the Murphy Wetland surface soil and sediments (and surface water as contaminants are released to the overlying water from the sediments). These contaminants may directly affect terrestrial and/or aquatic organisms

including invertebrates and amphibian larvae and/or may be transferred to vegetation or macroinvertebrates. The plants and invertebrates may subsequently be consumed by ecological receptors inhabiting the wetland potentially resulting in adverse impacts to these populations or to higher trophic levels.

Figure 4-2 presents a site conceptual model for the Site that details potential exposure pathways for ecological receptors inhabiting the Murphy Wetland.

A complete exposure pathway exists if the ecological receptors have contact with the COPEC in one or more medium and there is an exposure route (ingestion, dermal contact) to the receptor. Species groups most likely to receive potential exposures to site COPECs are those whose activities frequently bring them into direct contact with surface water, sediment and surface soil, that directly consume plants and/or detritus (dead plant material), or that feed upon species possessing one or both of these characteristics. Species were selected as indicators for exposure evaluation to represent various components of the food chain present at the Murphy Wetland.

4.2.3.2 Assessment Endpoints and Measurement Endpoints

Assessment endpoints represent an expression of an ecological attribute that is to be protected (EPA, 1996). The selection of the assessment endpoints considered the following:

- Existing habitats and species potentially present at the site.
- Contaminants present and their concentrations.
- Modes of toxicity to various receptors by contaminants.
- Ecologically relevant receptors that are potentially sensitive or likely to be highly exposed to life history attributes.
- Potentially complete exposure pathways.

Table 4-8 presents the assessment endpoints that were selected for important components of the Murphy Wetland communities identified within the Site. The selected assessment endpoints represent both community level endpoints (e.g., benthic macroinvertebrate diversity and productivity) and population level endpoints (e.g., survival, growth and reproduction of particular guilds such as omnivorous birds).

Measurement endpoints are used to evaluate responses of each assessment endpoint exposed to a stressor (EPA, 1997). The measurement endpoints proposed for the ERA are also presented in Table 4-8. The selected parameters represent both community and population level measures. A brief discussion of the proposed measurement endpoints for each assessment endpoint is presented below.

Community-based measurement endpoints were selected for community level assessment endpoints and evaluated via comparison of concentrations in site media to benchmark values (e.g., ambient water quality criteria, sediment quality benchmarks). For population level endpoints that assess receptor guilds present within the Murphy Wetland (as detailed in the site conceptual model), specific indicator species were selected as measurement endpoints.

The selection of indicator species is based on several factors including:

- Potential for contact with COCs.
- Sensitivity to COCs present at the site.
- Natural history information readily available to assess exposure and toxicity.
- Ecological relevance.
- Social or economic importance.

Based on these considerations, a variety of indicator species were selected as receptor species for the two habitats identified within the Murphy Wetland. Specific indicator species selected include the muskrat *(Ondatra zibethicus),* mallard (*Anas platyrhynchos*) and short-tailed shrew (*Blarina brevicauda*).

Water Column Macroinvertebrate Community Survival and Reproduction

Contaminants detected in surface water samples collected from the seasonally ponded portion within the Murphy Wetland were compared to chronic and acute ambient water quality criteria (EPA, 2009). If criteria are unavailable, adverse chronic and acute effect levels reported in the literature (Suter and Tsao, 1996) were used to evaluate the detected constituents. Acute AWQC and effect levels correspond to contaminant concentrations that would cause less than 50% mortality in 5% of exposed populations in a brief exposure. Chronic AWQC and effect levels are based on acute-chronic ratios between acute effects and chronic values that incorporate adverse effects on growth, reproductive success and survival over all or most of the lifecycle of the test organism.

Benthic Macroinvertebarate Community Diversity and Productivity

The evaluation of this assessment endpoint compared COPC concentrations within the sediment to applicable sediment quality guidelines associated with effects on benthic biota. Applicable guidelines for this evaluation included sediment Threshold Effect Concentrations (TECs) and Probable Effect Concentrations (PECs) (MacDonald et al., 2000), National Oceanic and Atmospheric Administration (NOAA) Effects Range - Low (ER-Ls) and Effect Range - Median (ER-Ms) (Long et al, 1995), Ontario Ministry of Environment and Energy (MOE) Lowest Effect Levels (LELs) and Severe Effect Levels (SELs) (Persaud et al., 1993), and Oak Ridge National Laboratory (ORNL) Sediment Secondary Chronic Values (SCVs) (Jones *et al.,* 1997).

Sediment contaminant concentrations below the lower thresholds (i.e., TECs, ER-Ls, and LELs) are unlikely to result in adverse impacts to the benthic community while concentrations above the upper thresholds (i.e., PECs, ER-Ms and SELs) are likely to limit the diversity and abundance of benthic biota.

Mammalian Aquatic Herbivore Survival, Reproduction, and Growth

Mammalian herbivores that use the seasonally ponded habitat were assessed by estimating exposure to the muskrat. The muskrat is a common aquatic species that is important to aquatic

systems by influencing aquatic vegetation density and diversity. The muskrat has a relatively high ingestion rate. Estimated contaminant exposure doses were compared to chronic survival, reproductive, or growth effect levels associated with both a NOAEL reported in the literature. An exposure dose that exceeds the chronic NOAEL indicates effects are possible.

Avian Aquatic Omnivore Survival, Reproduction, and Growth

Mallards were selected as an indicator species for omnivore waterfowl that may inhabit the aquatic cover types identified within the Study Area. The mallard is important ecologically as it disperses seeds of aquatic vegetation and is an important component in the diet of many predators. Mallards are exposed to contaminants as they forage on both plants and invertebrates within shallow areas of water and sediment. The mallard is also an important game species. Estimated contaminant exposure doses were compared to chronic NOAEL survival, reproductive, or growth effect levels reported in the literature. Exceeding the chronic NOAEL indicates effects are possible.

Mammalian Terrestrial Insectivore Survival, Reproduction, and Growth

The short-tailed shrew is common within a variety of terrestrial habitats. The shrew is generally a fossorial species with a small home range. The diet of the short-tailed shrew is comprised primarily of insects and other invertebrates with small vertebrates and plant matter also consumed. The short-tailed shrew represents a sensitive indicator for an insectivore species as it would be exposed to contaminants that accumulate in invertebrates, has a small home range, and has a high food intake rate relative to its body weight. Estimated contaminant exposure doses received by the shrew within the forested/scrub-shrub habitat and within the seasonally ponded area were compared to chronic NOAEL survival, reproductive, or growth effect levels reported in the literature. An exposure dose that exceeds the chronic NOAEL indicates effects are possible to individuals.

For each of the individual indicator species discussed above, the assessment endpoint references an impact on survival, growth or reproduction of a population. Adverse effects on populations can be inferred from measures associated with impaired survival, growth or reproduction. Some

COPEC exposures may be associated with sub-lethal effects that do not directly influence mortality or reproductive success. However, these sub-lethal effects may increase the probability of death or negatively influence behavior or reproduction by enhancing susceptibility to predation or parasitism, or weakening competitive ability. For this ERA, it is assumed that toxicity reference values representing sub-lethal and non-reproductive endpoints may indirectly affect the survival or reproduction of the exposed population, potentially leading to a reduction in study area populations.

4.3 Analysis of Ecological Exposure and Effects

The analysis component of the ERA consists of assessing the exposure of the selected assessment endpoint receptors to the COPECs (Exposure Characterization) and assessing the toxicity of the COPECs to the receptors (Ecological Effects Characterization).

4.3.1 Exposure Characterization

Exposure represents the contact (including ingestion) of a measurement receptor with a COPEC through the various exposure pathways identified in Section 4.2.3. Exposure to community measurement receptors (i.e., aquatic water invertebrates, benthic invertebrates) is simply represented by the concentrations of COPECs within the media of concern that the particular community inhabits. Surface water (dissolved and total) and sediment contaminant concentrations (mean and maximum) are provided in Appendix C. These concentrations are assumed to represent exposure point concentrations for these community receptors.

Exposure to contaminants via the food chain is evaluated by modeling exposure to the selected indicator species or measurement receptors (muskrat, mallard, and short-tailed shrew). The exposure scenarios developed in the Problem Formulation place receptor species within exposure pathways that are most likely to contribute to contaminant intake.

The muskrat may be exposed to sediment COPECs through direct ingestion and through consumption of vegetation and aquatic invertebrates that have accumulated contaminants through plant or invertebrate uptake. The short-tailed shrew may consume contaminants directly

through surface soil ingestion or indirectly via the consumption of invertebrates that are in direct contact with contaminated surface soil. The mallard would be exposed to Murphy Wetland COPECs through the ingestion of both vegetation and invertebrates that are in direct contact with contaminated sediment. The purpose of the exposure assessment is to formulate these exposure pathways into algorithms that can predict an estimate of total exposure.

The methods and calculations required for quantification of exposure doses are described within this section. Exposure to contaminants at the site by the selected indicator species is estimated by the following equation:

$$ED = [(S_{conc} \times S_{diet}) + (P_{conc} \times P_{diet}) + (I_{conc} \times I_{diet})] (FIR) (AUF) (TUF) + (W_{conc}) (WIR) (AUF) (TUF)$$

where:

ED = ...Exposure Dose (mg/kg-body weight-day);

S_{conc} = Sediment or surface soil COPEC concentration (mg/kg);
S_{diet} = % of diet sediment/soil comprises;
P_{conc} = Plant COPEC concentration (mg/kg);
P_{diet} = % of diet plants comprise;
I_{conc} = ... Invertebrate COPEC concentration (mg/kg);
I_{diet} = % of diet invertebrates comprise;
FIR = Food ingestion rate (kg/kg-body weight-day);
W_{conc} = Surface water (total) COPEC concentration (mg/L);
WIR = Water ingestion rate (L/kg BW-day);
AUF = Area use factor (% of home range comprised of habitat evaluated); and,
TUF = Temporal use factor (% of year habitat is used).

Dietary information for the muskrat, mallard and short-tailed shrew was obtained directly from the Aberjona River BERA (EPA, 2004). Specifically, food and water ingestion rates, dietary composition (relative percentage of vegetation and invertebrates in the diet as well as sediment ingestion rates) were obtained from the Aberjona River BERA. The model inputs for the muskrat, mallard and short-tailed shrew are presented in Tables 4-9 through 4-11, respectively.

4.3.1.1 COPEC Concentrations in Plants

Concentrations of COPECs in vegetation were determined by multiplying the mean and maximum (or 95% UCL, whichever is less) sediment or surface soil concentrations by the average plant uptake factors calculated within the Aberjona River BERA (EPA, 2004). For the few COPECs where a plant uptake factor was not provided (i.e., VOCs and dioxin-like PCB congeners), a plant uptake factor for organic COPECs was derived from Travis and Arms (1988). Plant uptake bioaccumulation factors and calculated mean and maximum plant tissue concentrations are presented in Table 4-12.

4.3.1.2 COPEC Concentrations in Invertebrates

Site-specific sediment data from the seasonally ponded area and surface soil data from the forested/scrub-shrub cover type were used to estimate COPEC body burdens within invertebrate prey. The concentrations of COPECs in invertebrates were estimated using different methods for inorganic and organic COPECs. For organic COPECs, an equilibrium partitioning model was used to estimate invertebrate body burdens. The basic assumption underlying this equilibrium partitioning model, presented in Sample *et al.* (1997), is that invertebrates are in equilibrium with the aqueous phase of soil.

For inorganic COPECs, regression equations relating contaminant concentrations in sediment or soil and invertebrate tissue (Bechtel Jacobs, 1998: Sample *et al.*, 1998) were used to estimate burdens of arsenic, cadmium, chromium, copper, lead, manganese, mercury, nickel, selenium, and zinc in invertebrates at the study area. Concentration factors for barium (0.36) and iron (0.38) (dry weight to dry weight), based on coupled analyses of soil and biota, were taken from Beyer and Stafford (1993). Uptake factors were not available for antimony, beryllium, thallium, and vanadium. An uptake factor of 0.5 (dry weight to dry weight) was assumed to estimate the concentration of these inorganics in worm tissue.

Calculated invertebrate COPEC concentrations for both the seasonally ponded and forest/scrub-shrub habitats, based on average or maximum sediment and surface soil COPEC concentrations are presented in Tables 4-13 through 4-16.

4.3.1.3 COPEC Exposure Estimation for Avian/Mammalian Receptors

For each of the avian/mammalian receptors, two exposure models were calculated, an average case scenario and a maximum case scenario. The average case scenario was a dietary exposure model based on mean concentrations of each COPEC calculated for sediment, surface water, and plant/invertebrate tissue as appropriate for the receptor. Arithmetic means of all of the sediment samples collected within the seasonally ponded area and all the surface soil samples collected from the forested/scrub-shrub cover types were calculated. The arithmetic mean of surface water samples collected from the seasonally ponded area was used to represent mean values for both habitats as surface water sampling data from the forested/scrub-shrub habitat are unavailable. The calculated mean sediment and surface soil concentrations were used to calculate mean plant and invertebrate tissue concentrations that were subsequently used to determine the total dose from dietary exposure to the muskrat, mallard and shrew.

The maximum, or acute exposure case scenario, was modeled by calculating the 95% upper confidence limit (95% UCL) for all of the sediment and surface soil samples collected within the seasonally ponded area and the forested/scrub-shrub cover types. The 95% UCL of the average concentration is the value that, when calculated for an infinitely large randomly selected set of subsamples, will equal or exceed the true average 95% of the time. The 95% UCL is frequently used in risk assessment to represent the reasonable maximum exposure (RME) to occur at a site. EPA recommends the use of the 95% UCL on the arithmetic mean concentration for the estimation of the RME risk in human health risk assessment (EPA 1989; 1992). Therefore, whenever possible, the 95% UCL has been calculated and used for the maximum exposure cases. The 95% UCLs were calculated using the EPA program "ProUCL Statistical Software". The 95% UCL values could be calculated by this program if a sufficient number of samples were available for summarization from a station or sample grouping. When too few samples were available, the program was unable to calculate a reliable 95% UCL value, and the maximum

sample concentration for the COPEC was used. Only three surface water samples were collected from the Murphy Wetland, therefore, the maximum surface water COPC concentrations were used for both habitats. Also, if the 95% UCL value was greater than the maximum detected concentration due to skewed distribution of the data, the maximum detected concentration was used. For the forested/scrub-shrub habitat, the 95% UCL value was nearly always greater than the maximum detected concentration due to skewed distribution of the data.

Sediment and surface soil ingestion rates were calculated by multiplying estimates of sediment/ surface soil ingestion found in the literature (expressed as a percentage of total food intake) by the food consumption rate. In cases where a species-specific sediment/soil ingestion value was not available in the literature, a value from a species with similar foraging habits was used.

It is important to note that an oral bioavailability factor of 1 was assumed for each chemical evaluated in the ingestion pathway. The use of a factor of 1 assumes that 100% of the chemical ingested in the diet is bioavailable, and that bioavailability is similar to that of the bioassay from which the toxicity reference value (TRV) is derived. Use of a factor of 1 also assumes that there is no difference in uptake of a chemical between that of the receptor species and the species from which the TRV was derived. The only exception to this assumption was for the bioavailability of arsenic from incidental sediment ingestion to the mammals (muskrat and shrew).

As seen from the swine study conducted in conjunction with the Aberjona River BERA (EPA, 2004), only approximately 50% of the arsenic in sediment fed to young swine was bioavailable. In the study, data were collected to calculate the relative bioavailability (RBA) of arsenic from site sediments. RBA is an estimate of the oral bioavailability to humans of arsenic from study area sediments compared to that of a reference arsenic compound administered in drinking water. “Best Estimate” RBA values determined in this study ranged from 37% to 51%, indicating that arsenic from sediments is absorbed less extensively than arsenic from drinking water. The most conservative RBA value determined for study area sediments (51%) was selected as the most appropriate to evaluate the oral toxicity of arsenic in sediments at all stations within the study area for mammals (muskrat and shrew). The site-specific RBA value of 51% was used to adjust the incidental sediment ingestion dose for each of the mammal indicator species (i.e., muskrat

and short-tailed shrew). The dose from plant material was not adjusted by this RBA, since no RBA for plants was derived.

Muskrat

The home range for a muskrat is relatively small, and consequently, the seasonally ponded area was assumed to provide all of a muskrat's foraging area throughout the year. The average and maximum case scenarios were calculated for all COPECs for the muskrat. Average and maximum (or 95% UCL) COPEC concentrations in sediment were used to estimate incidental sediment ingestion (2.4% of diet) and to estimate plant and invertebrate tissue concentrations (Tables 4-12 to 4-14). Dietary exposure for the muskrat assumes a diet comprised of 90% plant tissue and 10% invertebrates (see Table 4-9). Exposure from surface water ingestion was based on the average and maximum COPEC concentrations in surface water for the seasonally ponded habitat. The average and maximum exposure doses to the muskrat are provided in Tables 4-17 and 4-18, respectively.

Mallard

The home range of mallards is large, and can range from 40 to 1,440 ha (96 to 3,556 acres) (EPA, 1993). The 0.8-acre seasonally ponded area was conservatively assumed to provide 5% of a mallard's foraging area for 6 months of the year (the remaining portion of the year is considered to be unsuitable due to absence of surface water). For the mallard, the average and maximum case scenarios were calculated for all COPECs. Average and maximum (or 95% UCL) COPEC concentrations in the seasonally ponded habitat sediment were used to estimate incidental sediment ingestion (2.0% of diet) and to estimate plant and invertebrate tissue concentrations (Tables 4-12 to 4-14). Exposure from surface water ingestion was based on the average and maximum COPEC concentrations in surface water for the seasonally ponded habitat. Dietary exposure for mallard was based on 33% plant tissue and 67% invertebrates (see Table 4-10). The average and maximum COPEC doses ingested by the mallard are provided in Tables 4-19 and 4-20, respectively.

Short-tailed Shrew

The home range of a short-tailed shrew is small, on the order of less than one acre (EPA, 1993). The risk evaluation for shrew populations assumed that the forested/scrub-shrub and the seasonally ponded cover types may provide all of a shrew's foraging area. It is assumed that the seasonally ponded area would be accessible to small mammals for foraging during periods of drier weather (temporal use factor estimated at 0.67) while the forested/scrub-shrub habitat is accessible year-round.

Average and maximum (or 95% UCL) COPEC concentrations in sediment were used to estimate incidental sediment ingestion (13% of diet) and to estimate invertebrate tissue concentrations (Tables 4-13 through 4-16). Dietary exposure for the shrew assumes a diet comprised of 31% invertebrates with sediment ingestion representing 13% of the diet (EPA, 2004). Exposure from surface water ingestion was based on the average and maximum COPEC concentrations in surface water for the seasonally ponded habitat. The average and maximum COPEC doses ingested by the short-tailed shrew for the seasonally ponded habitat are provided in Tables 4-21 and 4-22, respectively, while average and maximum COPEC exposure within the forested/scrub-shrub cover types are presented in Tables 4-23 and 4-24, respectively.

4.3.2 Ecological Effects Characterization

Potential risk from exposure to COPECs was assessed by the comparison of calculated exposures to appropriate toxicity reference values (TRVs) for each of the receptors. Community-level TRVs are media specific (i.e., concentration in surface water or sediment) while TRVs for receptor species are provided in terms of dose ingested. The selected TRVs for each receptor are identified and discussed below.

4.3.2.1 Water Invertebrate TRVs

Aquatic invertebrates (as well as other organisms such as amphibians) present within the aquatic habitats provided by the seasonally ponded habitat of the Murphy Wetland may be exposed to surface water contaminants. A comparison of detected constituents within the surface water

samples with screening benchmarks protective of aquatic organisms was conducted in the selection of COPECs. A total of four inorganic constituents were detected in the surface water samples above their screening benchmarks. A review of additional toxicity data for these COPECs was conducted and included other water quality criteria (e.g., acute criteria), alternative screening values as well as additional effects levels reported in the scientific literature. Available toxicity data include both chronic and acute studies relating to adverse effects to aquatic invertebrates. The surface water TRVs for the aquatic invertebrate community are presented in Table 4-25.

Lowest chronic values for invertebrates (daphnids and nondaphnid invertebrates) were derived from Suter (1996) and represent chronic ambient water quality criteria for invertebrates (based on actual chronic test results with invertebrates) or are estimated based on the available acute toxicity test data (Suter, 1996). Another invertebrate benchmark obtained from Suter (1996) is the test daphid EC20 which represents the highest tested concentration resulting in less than a 20% reduction in the growth, fecundity or survival of daphnids through chronic exposure. The EC20 daphid benchmarks are intended to represent chronic indices of daphnid population production (Suter, 1996). The EPA Ecotox database was also reviewed to obtain additional toxicity data for various invertebrate species. In addition to the invertebrate-specific TRVs, water quality criteria (acute and chronic) were included as applicable TRVs.

4.3.2.2 Benthic Invertebrate TRVs

Aquatic invertebrates present within the aquatic habitat provided by the seasonally ponded portion of the Murphy Wetland may also be exposed to sediment contaminants. A comparison of maximum detected constituents within the sediment samples with screening benchmarks protective of aquatic benthic organisms was conducted in the selection of sediment COPECs. A total of 5 VOCs, 21 SVOCs, 5 pesticides, 2 PCB Aroclors, and 20 inorganic constituents were detected in the sediment samples above their screening benchmarks. A review of additional toxicity data for these COPECs was conducted and included alternative yet conservative screening values as well as additional effects levels reported in the scientific literature (e.g., probable effect concentrations for inorganic COPECs). Sediment TRVs used to evaluate

COPEC concentrations for their potential to result in adverse effects to benthic organisms inhabiting the seasonally ponded habitat are presented in Table 4-26.

TRVs for sediment COPECs primarily include Threshold Effect Concentrations (MacDonald et al., 2000). The Threshold Effect Concentration (TEC) represents a consensus-based freshwater benchmark below which adverse effects on benthic organisms are not expected (MacDonald et al., 2000). TECs essentially reflect the geometric mean of previously published sediment quality benchmarks that were developed as threshold guidelines for predicting toxicity to sediment-dwelling biota. These previously published guidelines include Threshold Effect Levels (TELs from Smith et al., 1996 and EPA, 1996), Lowest Effect Levels (LELs from Persaud et al., 1993), Effects Range – Low (ER-Ls from Long and Morgan, 1990), and Minimal Effect Thresholds (METs from EC, 1992). The resulting consensus-based TECs were then evaluated to determine their predictive ability to classify sediments as toxic or non-toxic (MacDonald et al., 2000). This evaluation concluded that sediment concentrations below the TECs had a low incidence of sediment toxicity and the TECs present an accurate basis for predicting the absence of adverse effects to benthic organisms inhabiting freshwater sediment (MacDonald et al., 2000).

If a TEC is unavailable for a sediment COPEC, then other conservative sediment quality benchmarks were selected. For inorganic COPECs, Threshold Effect Concentrations (Ingersoll et al., 1996) associated with effects on 28 day exposure to *Hyalella azteca* (an amphipod) or LELs (Persaud et al., 1993) were used as the sediment TRV. For antimony, an Upper Effect Concentration was used as the TRV since TECs or LELs are not available for this sediment COPEC. Sediment TRVs for those organic sediment COPECs (i.e., VOCs and SVOCs) that do not have TECs were selected on references (Fuchsman, 2003; Jones et al., 1997) that calculated TRVs based on chronic surface water quality benchmarks and equilibrium partitioning (EqP). The EqP approach is based on a correlation between contaminant concentrations in sediment, on an organic carbon basis, to their corresponding concentrations in the interstitial pore water of the sediment. The EqP approach assumes that the partitioning of the contaminant between the sediment and interstitial water are in equilibrium. The lowest organic carbon content of the seasonally ponded sediments (4.39 %) was used to determine the TRVs for these COPECs.

In addition to the TEC benchmarks, inorganic sediment COPEC TRVs also included a Probable Effect Concentration (PEC), if available. The PEC represents a consensus-based freshwater benchmark above which adverse effects on benthic organisms are expected (MacDonald et al., 2000). Similar to the TECs, the PECs reflect the geometric mean of five previously published sediment quality benchmarks that were developed as guidelines for predicting toxicity to sediment-dwelling biota. These previously published benchmarks include Probable Effect Levels (PELs from Smith et al., 1996 and from Ingersoll et al., 1996), Severe Effect Levels (SELs from Persaud et al., 1993), Effects Range – Median values (ER-Ms from Long and Morgan, 1990), and Toxic Effect Thresholds (TETs from EC, 1992). Similarly, the SEL (Persaud et al., 1993) was used as another sediment TRV for organic COPECs and for those inorganic sediment COPECs where a PEC is unavailable.

4.3.2.3 Wildlife TRVs

Wildlife toxicity reference values (TRVs) were selected to evaluate potential effects of the estimated exposure doses received by the selected avian and mammalian measurement receptor species (i.e., muskrat, shrew and mallard). The chronic No Observable Adverse Effect Level (NOAEL), if available for avian and mammalian species, was selected for assessing the effects of exposure by the measurement receptor species. If a chronic NOAEL was unavailable, then the chronic Lowest Observable Adverse Effect Level (LOAEL) reported in the scientific literature was adjusted by an uncertainty factor of 0.2 to derive a TRV equivalent to a chronic NOAEL (Wentsel et al., 1996).

Because toxicity data for the selected receptor species are unavailable, it is necessary to extrapolate toxicity data from other species, usually laboratory test animals. However, the test endpoints for the laboratory species must be significant to the measurement receptor species under field conditions. Endpoints that were considered significant for this risk assessment included adverse effects on growth, reproduction, and survival that are most likely to result in adverse effects to wild populations of receptors. The primary sources of avian and mammalian TRVs were from the TRVs presented in the EPA eco-SSL guidance documents. Additional sources of TRVs if unavailable in these eco-SSL documents included Sample et al. (1996) and

EPA (2002). TRVs selected for each COPEC for mammals and birds are presented in Tables 4-27 and 4-28, respectively.

Toxicity Equivalency Factors (TEFs) were used to equate dioxin-like toxicity of PCB congeners with 2,3,7,8-tetrachlorodibenzo-p-dioxin (2,3,7,8-TCDD) that represents the most toxic and extensively studied dioxin isomer. TEFs for birds and mammals used for each of the dioxin-like PCB congeners are presented in Table 4-29 (Van den Berg et al., 1998; 2006).

4.4 Risk Characterization

Potential risks to the selected measurement receptors from COPECs detected in the media of concern at the Site were evaluated by the hazard quotient method which compares estimated exposure doses with applicable toxicity reference values (TRVs). This comparison (expressed as a hazard quotient) is calculated for each COPEC as follows:

$$HQ = ED/TRV$$

where:

HQ = Hazard Quotient;
ED = Exposure Dose (from Section 4.3.1); and,
TRV = Toxicity Reference Value (from Section 4.3.2).

If the calculated hazard quotient is less than one, then it is unlikely that that contaminant will result in an adverse effect on that measurement receptor. Conversely, a hazard quotient greater than one indicates a particular measurement receptor may be at risk of an adverse effect from that contaminant. A Hazard Index is also calculated based on the sum of the COPEC-specific HQs to determine the risk from multiple stressors. It is important to note that HQs provide only a general characterization of potential impacts to the local biota. An HQ less than one is indicative of non-risk, however, an HQ greater than unity does not in itself represent an unacceptable risk. Other site-specific factors (e.g., bioavailability) present at the Site may affect the initial screening calculation.

4.4.1 Water Column Invertebrates Measurement Receptor

Risk to the water column macroinvertebrate community from the detected COPECs within the surface waters of the seasonally ponded area within the Murphy Wetland were assessed by comparing concentrations of the COPECs in surface water with criteria or benchmarks protective of aquatic life. In addition, surface water concentrations of these COPECs detected in the reference wetlands (EPA, 2004) were also compared to the surface water TRVs. The results of this comparison are presented in Table 4-30.

Total recoverable mean concentrations of aluminum, cyanide, iron and manganese exceed their respective chronic water quality criterion at surface water samples collected from the Murphy Wetland. In addition, the mean concentration of iron exceeds chronic effect levels associated with impacts to daphnids. None of the four COPECs exceeds their respective acute benchmarks.

Aluminum was detected in one of three samples at a concentration (244 ug/L) above its chronic water quality criterion of 87 ug/L, but below the other surface water TRVs for this COPEC. Toxicity of aluminum is related to pH with toxicity generally decreasing with increasing pH although this relationship is not well quantified at this time. The mean aluminum concentration (567 ug/L) detected in the wetland reference area surface water samples exceeds the maximum concentration detected in the Murphy Wetland suggesting that aluminum may not be a COPEC that is entirely associated with the Site but is representative of regional conditions. However, many high quality waters have elevated aluminum levels above the chronic water quality criterion (EPA, 2009).

Cyanide exceeds its chronic water quality criterion at two of three surface water samples but was not elevated above its acute water quality criterion or other surface water TRVs. Cyanide was not detected in the surface water samples collected from the reference wetlands. Therefore, cyanide levels detected within the seasonally ponded area of the Murphy Wetland potentially present a chronic risk to aquatic invertebrates present within this area.

Iron and manganese were both elevated above their chronic water quality criterion (1000 ug/L) or chronic Tier II benchmark (80 ug/L), respectively, at two of three surface water samples collected from the seasonally ponded area within the Murphy Wetland. Manganese was not detected above its acute Tier II benchmark while an acute water quality criterion for iron is not available. The mean iron concentration (3940 ug/L) and manganese concentration (650 ug/L) detected in the wetland reference area surface water samples exceed the mean and maximum iron and manganese concentrations detected in the seasonally ponded area of the Murphy Wetland suggesting that iron and manganese may not be COPECs that are entirely associated with the Site but are representative of regional conditions.

4.4.2 Benthic Invertebrate Measurement Receptor

Risk to the benthic macroinvertebrate community from the detected COPECs within the sediments of the seasonally ponded area within the Murphy Wetland were assessed by comparing concentrations of the COPECs in sediment with benchmarks protective of benthic biota. In addition, sediment concentrations of these COPECs detected in the reference wetlands (EPA, 2004) were also compared to the sediment TRVs. The results of this comparison are presented in Table 4-31.

Ethylbenzene exceeds its sediment TRV at one of the five samples where this COPEC was analyzed. Ethylbenzene was not detected in the reference wetland sediment samples. The remaining VOCs either were detected below their sediment TRVs (2-butanone and acetone) or sediment TRVs are unavailable (ethylene dibromide and MTBE).

At most sampling locations within the seasonally ponded area of the Murphy Wetland, PAHs were generally elevated above their lower benchmarks (e.g., TECs or LELs). However, concentrations of PAHs at all sampling locations within the Murphy Wetland were less than their higher benchmarks (e.g., SELs) that are typically associated with severe adverse impacts to the benthic macroinvertebrate community. In addition, detected concentrations of PAHs were usually higher in the reference wetland samples than noted within the Murphy Wetland suggesting that PAHs may be attributable to urban conditions in the vicinity of the Site. Phenol

was also detected above its respective TRV and the background level indicating adverse effects from this COPEC to the benthic community are also possible. However, as phenol was only detected in one of five samples above its TRV, any impacts may be localized within the wetland.

Although several pesticides (e.g., DDT and chlordane) were detected within sediments of the seasonally ponded area of the Murphy Wetland above their lower benchmarks (i.e., TECs), the concentrations of these COPECs were below both reference levels and higher benchmarks (e.g., SELs) associated with severe effects to the benthic community.

Total PCBs (sum of Aroclors 1254 and 1260) were both frequently detected above their lower and higher benchmarks (as well as reference wetland levels) indicating that these COPECs may potentially impact the benthic macroinvertebrate community. Total PCBs were detected above its SEL benchmark at 24% of the sediment samples within the seasonally ponded area of the Murphy Wetland. The elevated PCB Aroclor levels (mean concentrations of total PCBs result in HQ of 1.3 for the SEL benchmark) suggest severe impairment to the benthic macroinvertebrate community from these COPECs is possible.

Several inorganics including arsenic, cadmium, copper, iron and mercury were generally elevated above their lower TRVs (i.e., TECs and LELs) and reference concentrations but were generally detected below levels associated with severe adverse effects (i.e., PECs and SELs). However, the concentrations of chromium and lead within the sediments of the seasonally ponded area of the Murphy Wetland were typically elevated above their PEC TRVs (at approximately 90% of the sediment samples). In addition, the mean concentrations of chromium and lead were elevated over one order of magnitude above the PEC TRVs (i.e., HQs of 52 and 22, respectively) suggesting adverse effects to the benthic macroinvertebrate community are likely. Zinc was also elevated above its PEC TRV at four of five samples where this COPEC was analyzed. However, unlike chromium and lead, the mean and maximum concentrations of zinc were two or less times the PEC TRV.

Overall, the detected concentrations of several COPECs including total PCBs, chromium and lead within the sediments of the seasonally ponded area of the Murphy Wetland are substantially

elevated above TRVs associated with severe impairment of the macrobenthic invertebrate community. These COPECs are likely to adversely affect macroinvertebrates within this area by decreasing community diversity and/or abundance.

4.4.3 Mammalian Herbivore Measurement Receptor

Risks to the herbivorous muskrat from detected COPEC concentrations in the seasonally ponded area of the Murphy Wetland sediments and surface water (as well as modeled concentrations in aquatic vegetation and invertebrates) are presented in Table 4-32. The mean and maximum hazard indices (sum of hazard quotients for mean and maximum concentrations of all COPECs) are 150 and 350, respectively. However, the mean exposure dose represents a more realistic exposure scenario for the muskrat within the small area of habitat provided by the seasonally ponded area of the Murphy Wetland.

The elevated mean hazard index is primarily attributable to risk from dioxin-like toxicity from PCB congeners (HQ of 63 that provides 42% of the hazard index) and PCB Aroclors 1254 and 1260 (HQs of 10 and 20, respectively that total 20% of the hazard index) and. PCBs present within the seasonally ponded area of the Murphy Wetland are of concern to foraging mammals within this area as mean exposure doses are anticipated to exceed NOAEL TRVs by a considerable margin. Muskrat exposure to PCBs (both Aroclors and congeners) is primarily through ingestion of aquatic invertebrates rather than plant, water or incidental sediment ingestion.

The remaining COPECs with elevated HQs above one include lead (HQ is 36), chromium (HQ is 10), high molecular weight PAHs (HQ is 4), and antimony (HQ is 3). These four COPECs contribute approximately 35% of the mean hazard index and are of concern to foraging herbivores within the Murphy Wetland as muskrat exposure to lead and chromium is primarily from plant ingestion. Aquatic invertebrate ingestion represents the primary exposure route for antimony while HMW PAH exposure is due to approximately equal contributions plant and invertebrate ingestion. However, mean concentrations of HMW PAHs in the reference wetland are similar to concentrations noted in the Murphy Wetland indicating risk to foraging muskrats is

not expected to be significantly greater than regional risks from HMW PAHs. The mean HQ for zinc was 1 indicating that the exposure dose is approximately equal to the muskrat TRV. However, as the TRV is based on a NOAEL, adverse effects associated with a zinc dose equal to this TRV are not anticipated.

4.4.4 Avian Omnivore Measurement Receptor

Risks to the omnivorous mallard duck from detected COPEC concentrations in the seasonally ponded area of the Murphy Wetland sediments and surface water (as well as modeled concentrations in aquatic vegetation and invertebrates) are presented in Table 4-33. The mean hazard index (sum of hazard quotients for mean concentrations of each COPEC) is 3. The only COPEC that has a mean HQ at or above 1 is lead (HQ is 2). Mallard exposure to lead is through both plant and aquatic invertebrate ingestion with incidental sediment ingestion also contributing to the total exposure dose (see Table 4-19). The maximum doses of Aroclor 1260 and chromium ingested by the mallard result in HQs of 2 and 1, respectively. However, the mean exposure dose represents a more realistic exposure scenario for the mallard within the small area of habitat provided by the seasonally ponded area of the Murphy Wetland.

4.4.5 Mammalian Insectivore Measurement Receptor

Risks to the insectivorous short-tailed shrew from detected COPEC concentrations in the seasonally ponded area and the forested scrub-shrub areas of the Murphy Wetland sediments and surface water (as well as modeled concentrations within invertebrates) are presented in Tables 4-34 and 4-35, respectively.

4.4.5.1 Seasonally Ponded Area

The mean hazard index (sum of hazard quotients for mean concentration of each COPEC) is 160 with the major risk contributors represented by dioxin-like PCB congeners (HQ = 100 or 62% of total risk), PCB Aroclor 1254 (HQ = 16 or 10% of total risk) and PCB Aroclor 1260 (HQ = 26 or 16% of total risk). Other COPECs with mean HQs exceeding 1 include antimony, chromium and lead (HQs are each 5) and HMW PAHs (HQ = 3). As previously discussed, mean

concentrations of HMW PAHs in the reference wetland are similar to concentrations noted in the Murphy Wetland indicating risk to foraging shrews is not expected to be significantly greater than regional risks from HMW PAHs.

PCBs present within the seasonally ponded area of the Murphy Wetland are of concern to foraging mammalian insectivores within this area as mean exposure doses are anticipated to exceed NOAEL TRVs by a considerable margin. Shrew exposure to PCBs (both Aroclors and congeners) is primarily through ingestion of invertebrates with incidental sediment ingestion also contributing to the total exposure dose. The mean concentrations of antimony, chromium and lad are also of concern to foraging mammalian insectivores within the seasonally ponded area. Shrew exposure to chromium and lead is primarily from sediment ingestion with antimony exposure from both invertebrate and sediment ingestion.

Overall, the concentrations of PCB Aroclors and congeners and several inorganic COPECs (antimony, chromium, lead) within the sediments of the seasonally ponded area of the Murphy Wetland are expected to result in exposure doses to the shrew that exceed NOAEL TRVs indicating adverse effects are possible to insectivorous mammals.

4.4.5.2 Forest/Scrub-Shrub Area

The mean hazard index is 24 with the major risk contributors represented by chromium, PCB Aroclor 1254, PCB Aroclor 1260, and lead (HQs = 9, 7, 5 and 2, respectively). PCB Aroclors present within the forested/scrub-shrub area of the Murphy Wetland are of concern to foraging mammalian insectivores within this area as mean exposure doses are anticipated to exceed NOAEL TRVs. Shrew exposure to PCB Aroclors is primarily through ingestion of invertebrates.

The potential risk to the shrew attributable to inorganics is primarily associated with elevated HQs for chromium (HQ is 9) and lead (HQ is 2). These COPECs are of concern to foraging mammalian insectivores within the forested/scrub-shrub portion of the Murphy Wetland. Shrew exposure to chromium and lead is primarily from soil ingestion.

Overall, the concentrations of PCB Aroclors and chromium and lead within the soils of the forested/scrub-shrub area of the Murphy Wetland are expected to result in exposure doses to the shrew that exceed NOAEL TRVs indicating adverse effects are possible to insectivorous mammals within this habitat.

4.4.6 Refinement of COPECs for Mammalian and Avian Receptors

Based on the results of the risk characterization for the muskrat, mallard and short-tailed shrew, a number of the contaminants found at concentrations above screening-level concentrations and selected as COPECs, can be eliminated from further consideration for these herbivorous, omnivorous and insectivorous trophic level receptors. There were no indications of significant ecological risk from Site-related concentrations of VOCs, SVOCs or pesticides to any of these ecological receptors. PCBs Aroclors 1254 and 1260 and dioxin-like PCB congeners have elevated HQs for all three receptor species within the Murphy Wetland. Due to the negligible ecological risk to receptor species, ecological risk from VOCs, SVOCs and pesticides will not be evaluated further.

Among the inorganics identified as COPECs in surface water, sediment and/or surface soil in the Murphy Wetland, arsenic, barium, beryllium, cadmium, chromium VI, copper, cyanide, mercury, nickel, selenium, thallium and zinc did not have HQs greater than 1 for any mammalian or avian receptor species. No significant ecological effects appear to be associated with these COPECs to birds and/or mammals in the study area and these COPECs will not be considered further for contribution to ecological risk.

The dietary exposure models for the muskrat, mallard, and shrew resulted in HQs greater than 1 for PCB Aroclors and congeners, antimony, chromium and/or lead at either the seasonally ponded area and/or the forested/scrub-shrub area of the Murphy Wetland for most of these receptors. These remaining COPECs will be further evaluated for potential risk to one or more of the mammalian/ avian receptor species by using less conservative avian and mammalian LOAEL-based TRVs. LOAELs were derived from the same sources as were used to determine

the NOAEL TRVs. The LOAEL TRV represents an upper bound threshold effects level at which ecological impacts are predicted to occur. Where the average case scenario for exposure within the habitat area exceeds the LOAEL-based TRV, it is assumed that the COPEC represents a significant risk to receptor populations. The avian and mammalian LOAEL TRVs for the muskrat, shrew and mallard are presented in Table 4-36.

4.4.6.1 LOAEL Comparison of COPECs for Mammalian Herbivore Receptor

LOAEL risks to the herbivorous muskrat from detected COPEC concentrations in the seasonally ponded area of the Murphy Wetland sediments and surface water (as well as modeled concentrations in aquatic vegetation and invertebrates) are presented in Table 4-37. The mean hazard index is 25 with risk primarily attributable to PCB Aroclor 1260 (HQs is 11) with Aroclor 1254 and dioxin-like PCB congeners having HQs of 5 and 6, respectively. The LOAEL endpoints for Aroclor 1254 and the dioxin-like PCB congeners are associated with adverse effects on reproduction. The Aroclor 1254 LOAEL is based on dietary ingestion to old field mice (*Peromyscus poliontus*) that caused a reduction in the number of litters, offspring weight and offspring survival (Sample et al., 1996). The LOAEL for PCB congeners exhibiting dioxin-like toxicity is based on dietary ingestion that caused reproductive impairment to rats by reducing fertility and survival of offspring. The LOAEL endpoint for Aroclor 1260 was assumed to be the same as reported for Aroclor 1254. Overall, PCBs present within the seasonally ponded area of the Murphy Wetland are of concern to foraging mammalian herbivores within this area as mean exposure doses are anticipated to exceed LOAEL TRVs associated with reproductive impairment.

The mean HQ for chromium based on the LOAEL TRV is 2 while the remaining two inorganic COPECs (antimony and lead) have HQs less than 1. The LOAEL TRV for chromium was based on applying an uncertainty factor of 5 to a study that reported a NOAEL associated with growth rates in pigs receiving chromium their diet. Therefore, there is some uncertainty regarding whether chromium may also present a risk to muskrats inhabiting the seasonally ponded area of the Murphy Wetland.

4.4.6.2 LOAEL Comparison of COPECs for Avian Omnivore Receptor

The exposure dose of lead was the only COPEC predicted to exceed its NOAEL TRV for the mallard. Risks (based on a LOAEL TRV) to the omnivorous mallard from detected lead concentrations in the seasonally ponded area of the Murphy Wetland sediments and surface water (as well as modeled concentrations in aquatic vegetation and invertebrates) are also presented in Table 4-37. The mean HQ for lead based on the LOAEL TRV is less than 1 indicating risks are unlikely to omnivorous birds that forage within this area.

4.4.6.3 LOAEL Comparison of COPECs for Mammalian Insectivore Receptor

Risks based on LOAEL TRVs to the insectivorous shrew from detected (and modeled) COPEC concentrations in the seasonally ponded and forested/scrub-shrub areas of the Murphy Wetland are presented in Table 4-37. The mean hazard index is 33 for the seasonally ponded habitat. The elevated mean hazard index is primarily attributable to risk from PCB Aroclor 1260 (HQs is 14) with Aroclor 1254 and PCB congeners (dioxin-like toxicity) having an HQ of 8 and 10, respectively. As discussed above, the LOAEL endpoints for Aroclor 1254 and the dioxin-like PCB congeners are associated with adverse effects on reproduction while the LOAEL TRV for Aroclor 1260 is assumed to be similar to Aroclor 1254. Overall, PCBs present within the seasonally ponded area of the Murphy Wetland are of concern to foraging mammalian insectivores within this area as mean exposure doses are anticipated to exceed LOAEL TRVs associated with reproductive impairment. The mean HQ for chromium for the seasonally ponded area based on the LOAEL TRVs is 1, indicating a slight potential risk to shrews from this COPEC. However, as indicated above, the LOAEL TRV for chromium was based on applying an uncertainty factor of 5 to a study that reported a NOAEL associated with growth rates in pigs receiving chromium their diet. Therefore, there is some uncertainty regarding whether chromium may also present a risk. The remaining two COPECs (antimony and lead) have HQs less than 1. Therefore, adverse effects attributable to antimony and lead would appear unlikely based on an average exposure scenario.

For the forested/scrub-shrub area of the Murphy Wetland, the estimated exposure doses of Aroclor 1254 (HQ is 3) was predicted to exceed its respective LOAEL TRV associated with decreased reproduction in rats/mice. Therefore, a decrease in reproduction attributable to PCB Aroclor 1254 may present a risk to shrews inhabiting the forested/scrub-shrub area of the Murphy Wetland. PCB Aroclors 1260 and chromium (HQs = 3 and 2, respectively) may also present a risk although there is uncertainty associated with the LOAEL TRVs for these COPECs.

4.4.7 Uncertainty

There are considerable uncertainties associated with estimates of risk in any ERA, as the risk estimates are based on a number of assumptions regarding exposure and toxicity. There is uncertainty associated with the site conceptual model, with natural variation and parameter error, and with model error (EPA, 1997). A thorough understanding of the uncertainties associated with risk estimates is critical to understanding predicted risks and placing them in proper perspective.

Uncertainty associated with the conceptual model (Figure 4-2) includes assumptions about the selection of the receptors as representative of communities utilizing the habitats in the Murphy Wetland. Habitat quality for some of the receptor species appears marginal within portions of the Site and will influence actual presence or exposure of species or communities within the different portions of the Murphy Wetland. For example, the muskrat was selected as a herbivorous mammal that is likely to inhabit the seasonally ponded area of the Murphy Wetland. The assumption that the muskrat uses this ponded area throughout the year likely overestimated the exposure to sediment COPECs to herbivorous mammals. Therefore the calculated risk to muskrat populations is associated with high uncertainty.

4.4.7.1 Exposure Estimation

Exposure estimates for indicator species are a source of uncertainty in the ERA. Values for exposure parameters (*e.g.*, body weight, food intake rate, sediment ingestion rate) were based on literature values, not site-specific data. For instance, it was assumed, based on other studies, that

approximately 30% of the shrew diet is comprised of earthworms. It was also assumed that contaminant body burdens in earthworms are far greater than would be found in any of the other prey items shrews typically consume. The accuracy of each of these assumptions may be debated. However, the approach maintained in the ERA was to utilize conservative exposure parameters while maintaining a realistic evaluation of the potential for risk.

There is also uncertainty in using data collected in the Aberjona River BERA (EPA, 2004) to represent concentrations to which an indicator species may be exposed to at this Site. Plant tissue collected from one portion of the Aberjona River BERA study area were used to calculate uptake factors applied to this Site. However, using uptake factors derived from an adjacent site for each specific COPEC likely decreased the uncertainty over using literature values.

The bioaccumulative potential of plants varies among species, and even within different parts of the plant. Therefore, there are additional uncertainties in assuming the tissue concentrations from whole plants are representative of the exposure of a consumer, particularly for a species that might selectively graze on a specific species or part of a plant.

It is commonly assumed that the data used to characterize exposure (sediment, surface water or surface soil concentrations) are normally distributed. Ecological data, however, often do not fit a normal distribution, since they tend to have many low values and fewer high values. Since the mean is actually used in exposure estimated to represent a time-average, the arithmetic mean in some cases may over estimate exposure. Statistical analysis of the data used in the ERA revealed that some of the COPCE concentrations are not normally distributed, however, arithmetic means were still used to evaluate exposure. This was a conservative assumption and a source of uncertainty, since the arithmetic means are usually higher than geometric means, which are appropriate for log-normally distributed data. However, the relative magnitude of this uncertainty is likely small and would not significantly change the risk conclusions.

In general, there is high confidence that data collected for the ERA represent the types and distributions of sediment and surface soil contaminants within the seasonally ponded area of the Murphy Wetland at the Site. However, exposure estimates are always uncertain in that they are

driven by available data and by the methods used to collect those data. For example, exposure uncertainty is associated with the removal, prior to sampling, of coarse organic material (leaf litter or detritus) overlaying sediment or soil. Analytical data reflect the concentration of COPECs in sediment, and finer organic matter underlying the coarse organic matter at the surface. Therefore, analytical data may under- or overestimate exposures for invertebrates that inhabit or contact only coarse particulate organic matter at the substrate surface. Surface soil data within the forested/scrub-shrub portion of the Murphy Wetland are limited to PCB Aroclors and inorganics as VOC and SVOC data are unavailable for this area. However, as little risk to receptors from these COPECs was predicted within the seasonally ponded area of the Murphy Wetland, these COPECs are likely to provide minimal risk compared to the major COPECs at the Site that contribute risk: PCBs and chromium.

Conservative assumptions were also made about exposure duration and site use factors. Assumptions were made that exposure remains constant over the seasonal exposure duration of an individual animal. In fact, the home range of many species varies from one life stage to another. Migration of individuals in and out of the study area would also affect exposure duration. In particular, maximum exposure scenarios are very conservative, as they assume the highest sample concentrations for a contaminant was spread evenly over the entire range of an organism's residence or foraging range. With the exception of some benthic invertebrates, this assumption is very conservative, because none of the vertebrate species would likely be confined to an area representative of a single sample within the Murphy Wetland for a period of time approximating the exposure duration. Consequently, maximum exposure estimates for most of the models are worst-case scenarios that tend to grossly overestimate exposure.

4.4.7.2 Toxicological Data

Toxicity values for indicator species and communities were based on literature values. As is the case for literature-based exposure parameter values, this is a major source of uncertainty in the ERA. The sensitivity of receptors in the Murphy Wetland may be different than the sensitivity of species used in tests reported in the literature.

Assumptions about the equality of contaminant form between laboratory tests and site field conditions must also be made in the absence of speciation analyses. This is a source of uncertainty, since toxicity may vary with the form of the toxicant in the environment. Thus, the actual toxicities of COPECs evaluated in this ERA could be higher or lower than indicated by the TRVs used in the development of HQs.

Based on the review of available studies for which possible NOAEL or LOAEL TRV values were given, a large source of uncertainty is the selection of a TRV for estimation of HQs. The results of different studies often varied several orders of magnitude, based on using various forms of the COPEC, different species, and different endpoints. The selection of the geometric mean of these various studies was intended to reduce this uncertainty. One of the largest sources of uncertainty in all of these TRV values is the form of the chemical used to determine the laboratory exposure. The HQ approach uses the assumption that the absorption of the chemical from the diet will be the same as the absorption of the chemical in the form used in the laboratory. Often this assumption is very conservative, because absorption of metals ingested with sediment or plant material, is greatly reduced from forms given in laboratory studies.

One of the main uncertainties of the assessment is associated with the lack of toxicity values for the indicator species. For example, mammalian risks associated with iron in the sediment of the seasonally ponded area could not be evaluated due to the absence of an appropriate TRV. However, the mean concentration of iron detected in the sediments of the seasonally ponded area of the Murphy Wetland is similar to the iron levels detected in the reference wetlands (i.e., mean Murphy Wetland sediment concentration is less than 95% UCL iron level within reference wetlands). Therefore, risk attributable to iron is not expected to be significantly greater than regional risks from this COPEC. In addition, iron is an essential nutrient that may only be toxic to some organisms at very high concentrations. Toxicity values were also not available for calcium, magnesium, potassium and sodium for both avian and mammalian receptors. However, as these COPECs are essential nutrients, it is unlikely that these inorganics would present a significant risk to higher trophic level receptors that forage within the Murphy Wetland.

A considerable number of the COPECs for avian indicator species do not have an associated toxicity value. Therefore, an evaluation of these COPECs to provide risk to the mallard indicator species could not be provided. For avian species this would result in an underestimation of the total risk. For example, no avian toxicity value was found in the literature for VOCs. Therefore, it is unclear whether detected concentrations of these contaminants within site sediments may present a risk to avian species (as represented by the mallard) inhabiting the Site.

4.4.8 Summary

The sediment benchmark analysis indicated potential effects on benthic communities from total PCBs and from inorganics, especially chromium, lead, and zinc with the highest HQs attributable to PCBs, chromium and lead. Since the TRVs used for each of these COPECs was the PEC (probable effect concentration) they represent contaminant levels that potentially eliminate many of the benthic organisms within the community. Surface water concentrations of cyanide, are of concern as this COPEC exceeds its chronic water quality criterion but is less than its acute water quality criterion. Biological effects evaluations, in the form of sediment toxicity testing or benthic community structure were not undertaken for this ERA.

There was evidence of potential risk of impacts on the reproduction of muskrat due to the exposure to PCBs and chromium within the seasonally ponded area of the Murphy Wetland. There was low risk to mallard populations on the Site from exposure to lead. The risk to shrew populations from exposure to PCBs in sediment and surface soil was also present from detected concentrations of PCBs and chromium. However, the confidence in these conclusions is low, due to the high uncertainty associated with the estimation of these risks.

SECTION 4 TABLES

(SEE VOLUME II)

5.0 SUMMARY AND CONCLUSIONS

This section summarizes the findings and conclusions of the field investigation activities and baseline human health and ecological risk assessments conducted for the Southwest Properties (the Site) in Woburn, Massachusetts. The Site is part of the 2nd operable unit (OU-2) of the Wells G&H Superfund Site. The purpose of this report was to assess contamination at the Site and evaluate human health and ecological risks related to the contamination. The environmental setting, geology, surface hydrology, hydrogeology, nature and extent of contamination, fate and transport of contaminants, human health risk and ecological risk are summarized in the following text.

The Site is part of the Well G&H Superfund Site, which is comprised of approximately 330 acres bounded by Route 128/Interstate 95 to the north, the Boston and Main (B&M) Railroad to the west, Interstate 93 to the east and Salem and Cedar Streets to the south. The Site is situated within the southwestern corner of the Wells G&H Superfund Site, and primarily comprised of three parcels of land known as Aberjona Auto Parts (Aberjona property, 6.5 acres), Whitney Barrel (Whitney property, 2.7 acres), and Murphy Waste Oil (Murphy property, 3.6 acres), which are also listed as three separate MADEP BWSC "Chapter 21-E" sites. The Site is approximately 13 acres.

OU-2, also referred to as the Central Area, was identified by EPA in the September 14, 1989 Wells G&H ROD as an area requiring further evaluation. A RI/FS of the Central Area was undertaken by several Settling Defendants pursuant to a September 8, 1991 Consent Decree, which specified the obligations for each Settling Defendant, and specifically identified the three Southwest Properties (Aberjona, Whitney, and Murphy properties) as part of the Central Area. One of the objectives of the work required was to gather the data necessary for EPA to prepare a baseline risk assessment for the Southwest Properties and assess the need for remedial action.

This report presents the findings of the field investigations and the HHRA/ERA conducted at the Southwest Properties.

5.1.1 Site Description

The land use at and in vicinity of the Southwest Properties is highly developed with light commercial and light industrial parks bordering the wetlands area associated with the Aberjona River floodplain. Currently, the Aberjona property is a fenced auto storage yard (located within the former salvage yard) with an active auto repair establishment, a canine daycare operation, private athletic training facility and landscaping company as tenants of the former auto parts building. An existing residence is also present on the Aberjona property. An ice skating rink was recently constructed within the western portion of the property. The Whitney property is occupied by a variety of small businesses (e.g., landscaping, automotive glass company). The Murphy property is leased by CHES and registered as a TSDF under RCRA. The Murphy property is currently used for treatment and storage of waste oil. The Murphy Wetland lies between the upland portions of the Murphy, Whitney, Wildwood and Aberjona properties.

5.1.2 Geology/Hydrogeology

The area in the vicinity of the Southwest Properties Site is located within the southwestern portion of the Wells G&H Superfund Site and associated Aberjona River Valley. The Site is generally underlain by unconsolidated glacial deposits that unconformably overlie crystalline bedrock. The unconsolidated deposits at the edges of the Aberjona River Valley are primarily ground moraine deposits.

The natural overburden within the Southwest Properties is composed of stratified drift and swamp deposits (RETEC, 2003). The Southwest Properties are underlain by a basal glacial till, stratified drift deposits and a thin, relatively continuous layer of fill material near the ground surface (RETEC, 2003). The stratified drift consists of interbedded sand, gravel, silt and swamp deposits in select areas of the Site. The fill layer generally consists of light gray to dark brown sand mixed with subangular gravel, silt and/or varying amounts of brick, metal and wood debris (RETEC, 2003).

As indicated in the Supplemental RI Report (RETEC, 2003) and consistent with the previously noted axis of the buried bedrock valley in the approximate area of the Aberjona River, the

bedrock surface slopes from west to east across the Wildwood property and southern and western portion of the Southwest Properties. The bedrock surface mapped by RETEC also indicates a sub-trough extending approximately north-south beneath the Aberjona property. Bedrock at the Southwest Properties has been described as consistent with the Central Area and generally includes shallow metamorphosed diorite and granitic intrusions overlaying gabbro-diorite (Murphy property), green and gray gabbro-diorite (Whitney property) and gabbro-diorite transitioning to grano-diorite (Aberjona property) based on data evaluated during the Supplemental RI (RETEC, 2003). The hydraulic conductivity of the bedrock is generally low and, in general, potential well yields would be low.

Groundwater in the stratified drift is unconfined, and water levels fluctuate continuously in response to recharge and discharge. The water table is generally at or near the ground surface in most of the low-lying areas. The direction of groundwater flow is typically inward toward the central axis of the river. Under non-pumping conditions, groundwater discharges to the river and adjacent wetlands.

With respect to the Southwest Properties, groundwater flow is generally to the east, towards the Aberjona River in both unconsolidated soils and shallow bedrock. However, monitoring well gauging data collected throughout the Southwest Properties, Wildwood property and Central Area between 2011 and 2013 indicate an apparent transient mixing zone along the boundary between the Southwest Properties and the Wildwood property. At times, shallow groundwater appears to originate from the Southwest Properties, while at other times shallow groundwater appears to originate from the Wildwood property and flow toward the northern boundary of the Southwest Properties. For the deeper overburden and shallow bedrock, the October 2011 and July 2013 well gauging data suggest that the groundwater flow patterns are more consistently in an east to northeasterly direction, suggesting that the dominate groundwater flow patterns in these portions of the aquifer are from the Wildwood property toward the northern portion of the Southwest Properties.

Depth to groundwater at the Southwest Properties varies seasonally, and with proximity to the river and wetland, but generally ranges from 5 to 9 feet from the ground surface in upland portions of the site.

5.1.3 Field Investigation

Environmental data used in the preparation of this human health and ecological risk assessments were collected during several sampling events conducted by, or on behalf of, property owners (i.e., Clean Harbors), Settling Defendant (Beatrice) and split samples collected on behalf of EPA. The data, scope and location of investigative activity vary by property.

A Supplement Remedial Investigation was conducted by the Settling Defendant to update and supplement data previously collected at the Southwest Properties. The results of the Supplemental RI are documented in the *Supplemental Remedial Investigation Report, Southwest Properties, Wells G&H Superfund Site, Woburn, Massachusetts*, prepared by the RETEC on behalf of the Beatrice Company (RETEC, 2003).

On behalf of EPA, TRC performed oversight of the Settling Defendant's Supplemental Remedial Investigation, including split-sampling. The results of the split-sampling performed by TRC are documented in TRC's split-sampling report. (TRC, 2004)

In response to EPA's May 14, 2009 draft comment letter on the 2003 Supplemental RI (Appendix E.4) for the Southwest Properties, AECOM conducted additional investigation and evaluation activities at each of the properties between 2010 and 2013, including two rounds of subslab soil gas and indoor air sampling at the existing Aberjona residence in 2013. The primary objectives of the Supplemental RI were to address data gaps identified in previous investigation activities and evaluate current contaminant conditions at the Site. A description of the Supplemental RI is provided in AECOM's work plan (AECOM, 2010) and a brief summary is provided in the preceding sections of the text.

5.1.4 Nature and Extent of Contamination

The contaminant sources at the Site tend to be related to the extensive history of industrial and commercial use at each of the Southwest Properties, including operation of the Aberjona property for automotive repairs and storage, Whitney property for drum and tank refurbishment, and Murphy property for virgin and waste oil handling facility. Ongoing IRA activities being conducted at the Murphy property related to LNAPL associated with the former "oil yard" and "oil pit" also have the potential to impact the wetlands. LNAPL has also recently been detected to the rear of the Whitney building and is likely related to former onsite operations (e.g., barrel washing, use of drain lines, etc.). The Southwest Properties are also potentially influenced by off-site sources of contamination. For example, the Murphy Wetland has likely been influenced by impacts originating from neighboring properties including the former J.J. Riley Tannery and Wildwood property. VOC detections in groundwater have also likely been influenced, in part, to migration from additional upgradient sources (e.g., Wildwood Property).

Analytical data has been obtained from several environmental investigations encompassing the Southwest Properties and have included samples collected from surface soil/subsurface soil, sediment, groundwater, surface water, subslab soil gas and indoor air. Contaminants of potential concern at the Site include VOCs, PAHs, pesticides, PCBs, dioxin-like PCB congeners, petroleum hydrocarbons and metals. Analytical results generally indicate impacts are consistent with the historic use of each of the Southwest Properties. However, select media (e.g., sediment and surface water) within portions of the Site may be influenced by external factors independent of specific historic property usage.

The distribution of chemical impacts is influenced, in part, by factors such as the physical and chemical properties of the chemicals, geochemical reactions, the nature and location of sources, and Site characteristics such as geology, hydrology, and topography. Characteristics of these compounds that influence fate and transport processes and affect migration include specific gravity, water solubility, vapor pressure, Henry's Law constant, organic carbon partition coefficient and log octanol/water partition coefficient. The majority of the chemicals detected at

the Southwest Properties have specific gravities greater than 1. Contaminant groups such as PAHs, PCBs and metals also generally exhibit a relatively low level of water solubility, low vapor pressure and low volatility. Impacts such as PAHs and PCBs tend to exhibit relatively high K_{oc} values and K_{ow} values. Metals tend to be less likely to bind to soil and have a higher potential to leach into groundwater. Contaminant groups such as non-chlorinated VOCs and select petroleum hydrocarbons tend to exhibit specific gravities less than 1. These contaminant groups exhibit a range of solubility from low to relatively high, and tend to exhibit higher vapor pressures and higher relative volatility when compared to the PAHs, PCBs and metals. These contaminant groups tend to exhibit low K_{oc} values, indicating a high potential to leach, and are compounds are more likely to bind to soil based on the log K_{ow} values.

The discussion in Section 2.0 summarizes, on a site-specific basis, how the contaminants entered the environment, how the contaminants were likely transported at the Site, and the potential for exposure to human and environmental receptors, as currently supported by the available data, information on contaminants identified at the Site, and contaminants properties. Surface and subsurface soil and air impacts throughout the Site are generally believed to be associated with direct placement/discharge associated with historic site activities. Impacts to groundwater, sediment, surface water and the food chain are consistent with more complicated migration pathways potentially including both on-site and off-site impact sources.

5.1.5 Baseline Human Health Risk Assessment

The baseline human health risk assessment was performed to evaluate the potential for adverse health effects to human populations who may come into contact with contaminants present in environmental media at the Southwest Properties. A summary of the data utilized is provided in Table 5-1. Exposures were evaluated for the following media: surface and subsurface soil, groundwater, outdoor trench air, indoor air, surface water, and sediment. Chemicals of Potential Concern (COPCs) for the environmental media were identified for the properties and wetland area that compose the Southwest Properties (Aberjona, Whitney, and Murphy properties and the Murphy Wetland) and the existing Aberjona residence vapor intrusion indoor air pathway which were quantitatively evaluated under current and/or future land-use conditions. MassDEP

prepared a Groundwater Use and Value Determination (MassDEP, 2004; EPA, 2004 and 2005) for the Wells G&H Superfund Site in accordance with 1998 Memorandum of Agreement between EPA and MassDEP. MassDEP concluded a "medium" groundwater use and value determination was appropriate for the Wells G&H aquifer because of its significant current and future ecological value to the Aberjona River and associated wetlands and its potential human value as a drinking water supply in the future. Based upon this determination, future site-wide residents potentially exposed to groundwater used as potable water in the future was quantitatively evaluated under future land-use conditions.

More COPCs were identified than identified in the 2006 baseline risk assessment. The increase in soil and groundwater COPCs is due to changes in RSLs since 2006, additional sampling conducted between 2010 and 2013 to more accurately characterize potential soil source areas at each of the properties and the more analytically comprehensive data collected for soil and groundwater which reduces the uncertainty associated with the baseline risk assessment.

The arsenic bioavailability study that was performed as part of the Aberjona River Study Baseline Risk Assessment (EPA, 2004), which can be found in EPA's Draft Final MSGRP RI Report (EPA, 2005), was also used in this risk assessment. The arsenic bioavailability study was completed to assist in the quantification of sediment risks. This site-specific bioassay determined that arsenic is absorbed less efficiently from sediment than from a water medium. The most conservative relative bioavailability estimate from the study was used in this risk assessment to quantify sediment ingestion risks at the Murphy Wetland.

Site-specific hexavalent chromium data were collected and used in the risk assessment to more accurately characterize soil, groundwater, and sediment risks at the Southwest Properties. Only hexavalent chromium data obtained using the ion chromatography method for soil/sediment and Method 7196A for groundwater were quantitatively evaluated in the human health risk assessment.

Possible human exposure to the selected COPCs was characterized through exposure pathways for current and future land use. Current land use is commercial/industrial at all three sites,

except for the residence on the Aberjona property. The Southwest Properties are zoned industrial (City of Woburn, 2012) and portions of each property are within the mapped 100-year floodplain (City of Woburn, Tax Map #37 and #38, 2013). Many of the on-site areas of known contamination are currently fenced or covered with pavement. However, access to surface soil is not limited for the Whitney property. In addition, commercial workers may access the secured areas. Based on this information, current receptors include commercial workers at all three properties, trespasser at the Whitney property and Murphy Wetland, and residents potentially exposed to VOC-impacted indoor air at the existing Aberjona residence. Future receptors for all three properties include commercial workers, trespasser, recreational users and construction worker, including exposure to shallow groundwater contaminants during excavations at each of the three properties. The existing Aberjona residence is evaluated for impact to indoor air via the vapor intrusion pathway. The future site-wide residential scenario is evaluated for exposure to groundwater.

Whenever possible, 95% UCLs, calculated using EPA's software ProUCL (EPA, 2002; 2011; 2013b), were used as exposure point concentrations. Two sets of quantitative exposure estimates were prepared, corresponding to sets of exposure assumptions designated as central tendency exposure (CTE) and reasonable maximum exposure (RME) scenarios.

The potential for adverse health effects was evaluated by comparing the estimated incremental lifetime cancer risks (ILCRs) to the target risk range of 10^{-6} to 10^{-4} and the calculated hazard indices (HIs) for noncarcinogenic health effects to the target risk level of 1. Table 5-2 presents a risk summary for the Southwest Properties, with HIs and ILCRs summarized by property for surface soil, subsurface soil, groundwater, surface water, sediment, outdoor trench air and indoor air, as applicable, for each of the receptors evaluated. When risks were estimated for a child and adult receptor, the child HIs are presented on Table 5-2 as the most conservative, while ILCRs presented on Table 5-2 are the sum of the child and adult risks (i.e., a total receptor cancer risk). The medium-specific risks presented by property have been summed together, as appropriate, when a receptor would be exposed to more than one medium. The Murphy Wetland area was evaluated as a separate exposure point because of its location (i.e., located mostly on the Whitney and Murphy properties). The existing Aberjona residence was also evaluated as a

separate exposure point for the vapor intrusion pathway. In cases where the total pathway HI exceeded 1, COPCs having similar systemic effects were summed for each pathway and medium. Table 5-2 also summarizes the risk contributors (ILCR > 10^{-6}; HI > 1) for those receptors with estimated total ILCRs greater than 10^{-4} and target organ-specific HIs greater than 1. Figure 5-1 provides a site plan summarizing the RME human health risks.

More risk-contributing chemicals were identified in this baseline risk assessment than identified in the 2006 baseline risk assessment. The increase in risk-contributors is due to changes in toxicity values that have occurred since 2006, additional soil sampling conducted in 2010 and 2011 to more accurately characterize potential source areas at each of the properties and the more analytically comprehensive data collected for soil and groundwater which reduces the uncertainty associated with the baseline risk assessment.

5.1.5.1 Reasonable Maximum Exposure Based Risk

The media for which RME exposures for one or more pathways were within or below EPA's target risk range for carcinogens (ILCR of 10^{-6} to 10^{-4}) and risk criterion for noncarcinogens (HI of 1) are summarized below by exposure point (Aberjona Property, Whitney Property[9], Murphy Property, Murphy Wetland and Site-Wide Future Resident).

Aberjona Property

- All RME ILCRs and HIs are below criteria including current and future residents exposed to vapor intrusion pathway VOCs in indoor air at the existing Aberjona residence

[9] Worker protective measures should be used if excavation work is performed prior to remedy implementation near the rear of the building in the vicinity of the drain line connecting the former Whitney drum storage area to the municipal sewer system. During test pit excavation activities in this area in 2011, odors were observed and workers were outfitted with half-faced respirators with organic vapor cartridges due to elevated VOC readings.

Whitney Property

- Surface Soil (Current/Future Older Child Trespasser, Current/Future Commercial Worker, Future Construction Worker)

Murphy Property

- Surface Soil (Current/Future Older Child Trespasser, Current/Future Commercial Worker, Future Construction Worker)
- Subsurface Soil (Future Construction Worker)

Murphy Wetland

- Surface water (Current/Future Older Child Trespasser, Future Adult/Child Recreational User)
- Sediment (Current Older Child Trespasser)

The media for which RME exposures for one or more pathways exceeded the target risk range for carcinogens and/or noncarcinogens are summarized below:

Whitney Property

- Surface Soil (Future Adult/Child Recreational User)
- Subsurface Soil (Future Adult/Child Recreational User, Future Construction Worker)
- Shallow Groundwater (Future Construction Worker)

Murphy Property

- Surface Soil (Future Adult/Child Recreational User)
- Subsurface Soil (Future Adult/Child Recreational user)
- Shallow Groundwater (Future Construction Worker)

Murphy Wetland

- Sediment (Future Older Child Trespasser, Future Adult/Child Recreational User)

Site-Wide Future Resident

- Tap/Household Water (Future Adult/Child Resident)

The contaminants responsible for driving risk for the RME case above the target risk ranges are summarized below by exposure point. Contaminants that are major contributors to risk (ILCRs $>10^{-4}$ or HIs >1, or the contaminant with the greatest cancer risk) are shown in ***boldface italics***.

Whitney Property

- Surface Soil (vinyl chloride, benzo(a)anthracene, benzo(b)fluoranthene, ***benzo(a)pyrene***, indeno(1,2,3-cd)pyrene, dibenz(a,h)anthracene, ***total PCBs***, PCB TEQ, chromium (VI), arsenic)
- Subsurface Soil (vinyl chloride, trichloroethene, bis(2-ethylhexyl)phthalate, benzo(a)pyrene, dibenz(a,h)anthracene, alpha-chlordane, gamma-chlordane, alpha-BHC, ***heptachlor***, heptachlor epoxide, dieldrin, 4,4'-DDD, 4,4'-DDT, ***total PCBs, PCB TEQ***, chromium (VI), arsenic)
- Shallow Groundwater (***cis-1,2-dichloroethene, tetrachloroethene, trichloroethene***)

Murphy Property

- Surface Soil (***thallium***)
- Subsurface Soil (***thallium***)
- Shallow Groundwater (***cis-1,2-dichloroethene***)

Murphy Wetland

- Sediment (***C11-C22 aromatics, total PCBs***)

Site-Wide Future Resident

5.1.5.2 Central Tendency Exposure Based Risk

The media for which CTE exposures for one or more pathways were above EPA's target risk range for carcinogens and/or non-carcinogens are summarized below by exposure point:

Whitney Property

- Subsurface soil (Future Adult/Child Recreational User and Future Construction Worker)

Murphy Wetland

- Sediment (Future Adult/Child Recreational User)

Site-Wide Future Resident

- Tap Water/Household Water (Future Adult/Child Resident)

The contaminants responsible for driving risk above the target risk ranges in the CTE case are summarized below by exposure point. Contaminants that are major contributors to risk (ILCRs $>10^{-4}$ or HIs >1) are shown in ***boldface italics***.

Whitney Property

- Subsurface Soil (***total PCBs, PCB TEQ***)

Murphy Wetlands

- Sediment (***total PCBs***)

Site-Wide Future Resident

- Tap Water/Household Water (benzene, 1,4-dichlorobenzene, 1,1-dichloroethane, ***cis-1,2-dichloroethene,*** 1,4-dioxane, ***1,1,2-trichloroethane, 1,2,4-trichlorobenzene, trichloroethene, vinyl chloride, C9-C12 aliphatics, C9-C18 aliphatics,*** benzo(a)pyrene, ***naphthalene,*** PCB TEQ, ***total PCBs***, aldrin, alpha-BHC, heptachlor, ***arsenic, manganese***)

Lead in soil and sediment was evaluated through the use of EPA models for children and adults. For adult exposures to soil and sediment, the calculated central estimate of the blood lead concentration in women of childbearing age did not exceed the goal of 4.2 µg/dL for current and future land use. Likewise, assumed childhood lead exposures to soil were not estimated to result in blood lead levels exceeding the goal of 10 µg/dL. However, the lead evaluation for sediment in the Murphy Wetland indicates that future young child recreational exposures could result in childhood blood lead levels in excess of blood lead level goals. The highest lead concentrations in the Murphy wetland are located at sampling locations SW-2 (35,100 mg/kg), P-12 (24,900 mg/kg), P-14 (16,800 mg/kg), MR-11 (12,000 mg/kg) and P-43 (11,100 mg/kg). In addition, the maximum concentration of lead detected in groundwater (129 µg/L) exceeded the SDWA action level of 15 µg/L. The elevated lead levels in sediment may be impacting shallow groundwater in the vicinity of monitoring wells MW-24, MW-16 and MW-18S which displayed groundwater

lead concentrations in excess of the Safe Drinking Water Act (SDWA) action level (129 µg/L, 36.2 µg/L and 16.8 µg/L, respectively) and are located within or adjacent to the Murphy Wetland.

Arsenic was selected as a major contributor to the cancer risk for the future recreational user at the Whitney property due to ingestion of, and dermal contact with surface and subsurface soil. Potential historical releases of arsenic in surface soil at the Whitney property cannot be distinguished from background and therefore arsenic is not considered to be a major contributor to risk for this property. However, arsenic in subsurface soil at location WB-201 (3-5' and 5-6') are significantly elevated above background subsurface soil concentrations. Therefore, the arsenic concentrations at this location appear to be attributable to a site-related release rather than associated with a background condition.

Background surface and subsurface soil data for thallium were compared to soil data for the Murphy property where thallium was identified as a risk contributor. Thallium was not detected in background soils with reporting limits ranging from 0.14 mg/kg to 0.16 mg/kg. Thallium was detected in surface soil at concentrations ranging from 0.054 mg/kg to 10 mg/kg, and in subsurface soil from 0.069 mg/kg to 30 mg/kg. Five locations (one surface soil location; 4 subsurface soil locations) have thallium concentrations above the non-detect background levels identified for soil (B-18 [0-2'], B-10 [6-10' and 10-14'], B-5 [13-15'], B-8 [7-8' and 8-12'] and B-9 [6-10']). Therefore, it appears that thallium at these Murphy property surface and subsurface locations are not associated with background conditions at the site.

Should a change in land use at the Southwest Properties be contemplated that would include activities and uses not evaluated in the risk assessment, further evaluation will be required to assess the risks associated with the proposed land use change, including use of groundwater for purposes not identified in the risk assessment. In addition, the future vapor intrusion pathway will require further evaluation if a change in usage of any of the existing commercial buildings is contemplated that would result in higher occupancy (e.g., full-time commercial use of the Whitney or Murphy buildings or daycare use of the Aberjona building), or as part of new building construction including any addition to existing buildings on any of the properties. Use

of a vapor barrier or subslab system may be appropriate to mitigate the vapor intrusion pathway in instances of future development/construction of occupied buildings.

Though TCE, PCE and chloroform were not found at significant concentrations for resident exposure in any indoor air samples at the existing Aberjona residence, subslab soil gas concentrations of these compounds are greater than EPA soil gas screening levels for residential properties, with the subslab soil gas concentrations of TCE being the most elevated. The presence of elevated concentrations of VOCs, in particular TCE, in subslab soil gas beneath the existing Aberjona residence indicates a potential for future vapor intrusion to occur if building conditions were to change.

5.1.6 Ecological Risk Assessment

The effects-based screening resulted in the selection of 4 COPECs in surface water (all inorganics), 53 COPECs in sediment (5 VOCs, 21 SVOCs, 7 pesticides/PCBs, and 20 inorganics), and 11 COPECs in surface soil (2 PCB Aroclors and 9 inorganics) for evaluation in the ERA. Five indicator species or indicator communities were selected to evaluate risks associated with exposure to the COPECs in the surface water and sediment/surface soil of the Site. Endpoints in the ERA were selected to represent ecological attributes that are to be protected (assessment endpoints) and a measurable characteristic of those attributes (measurement endpoints) that can be used to gauge the degree of impact that has or may occur.

Each endpoint has associated with it a magnitude of risk and a degree of uncertainty. The magnitude of risk incorporates both the degree to which the endpoint was exceeded and also the proportion of the habitat affected. If the NOAEL TRV (lower effects threshold) was exceeded at the site, the contaminant was concluded to pose a low risk to populations. The highest risk was associated with contaminants that exceeded upper threshold effects levels based on LOAEL TRVs. If high HQs were present only for the maximum (or 95% UCL) COPEC concentration, the magnitude of the overall risk to the population from exposure to the COPEC was considered low.

The uncertainty associated with the estimation of risk, summarized in section 4.4.7, was qualitatively assessed, and based on many factors. A major source of uncertainty for mammalian and avian indicators was the relevance of the available TRVs. High uncertainty was also associated with COPECs that had corresponding high concentrations at reference locations. In cases where the magnitude of risk was low, and was associated with high degree of uncertainty, the overall risk for that endpoint was considered negligible.

Based on the analysis of the five selected indicators/endpoints in the ERA, there were no indications of significant ecological risk associated with VOC, SVOC and pesticide contamination within the Murphy Wetland. However, the ERA suggests that PCBs (both Aroclors and dioxin-like congeners) may pose current and future risks to the mammalian indicator populations of herbivores and/or insectivores as represented by the muskrat and short-tailed shrew, respectively. In addition, chromium may also pose risk to mammalian herbivores and insectivores foraging within the seasonally ponded area and mammalian insectivores foraging within the forested/scrub-shrub wetland. Risks to avian omnivores as represented by the mallard are expected to be low.

Analysis of the mean exposure assessment for muskrat indicated HQs greater than 1 based on NOAEL TRVs, for HMW PAHs, PCB Aroclors 1254 and 1260, dioxin-like PCB congeners, antimony, chromium, and lead. The mean estimated exposure to antimony and lead does not exceed the upper effect level based on the LOAEL TRV. However, mean exposure doses of PCB Aroclors 1254 and 1260, PCB congeners (exhibiting dioxin-like toxicity), and chromium estimated to be ingested by the muskrat result in HQs above 1 based on LOAEL TRVs. Due to the elevated HQs (particularly for PCB Aroclor 1254), the magnitude of the risk for muskrat exposure to these COPECs is high. These results indicate a potential impact on reproduction of mammal populations such as muskrat exposed to PCBs in the diet while foraging in the seasonally ponded area of the Murphy Wetland.

The mallard was used to represent waterfowl having relatively high exposure to sediments. Based on NOAEL TRVs, lead represented the only COPC to have a HQ greater than 1 for the Site based on the average exposure case. The concentrations of lead indicated low risk for

reduction in reproduction or sublethal effects to populations, but there was no evidence for high risk to populations since the lead LOAEL HQ was less than 1. The assessment of the waterfowl endpoint indicates a low risk to the sub-population of mallards at the seasonally ponded area of the Murphy Wetland from exposure to lead. The magnitude of the risk to mallard populations from lead was low since it is based on the NOAEL TRV value, which represents the threshold for effects for potential impacts to populations.

Short-tailed shrew exposure models were used to evaluate potential risk to small mammal populations living in and near the Murphy Wetland. Analysis of the mean exposure assessment for shrew indicated HQs greater than 1, based on NOAEL TRVs, for HMW PAHs, PCB Aroclors 1254 and 1260, dioxin-like PCB congeners, antimony, chromium, and lead at the seasonally ponded area of the Murphy Wetland while PCB Aroclors 1254 and 1260, chromium and lead have HQs greater than 1 (also based on NOAEL TRVs) at the forested/scrub-shrub area of the Murphy Wetland. The mean estimated exposures to antimony and lead do not exceed the upper effect level based on their respective LOAEL TRV at either habitat within the Murphy Wetland. However, mean exposure doses of dioxin-like PCB congeners, PCB Aroclors 1254 and 1260 and chromium estimated to be received by the shrew at the seasonally ponded and PCB Aroclors 1254 and 1260 and chromium at the forested/scrub-shrub areas result in an HQ at or above 1 based on their LOAEL TRVs. Due to the elevated HQs (particularly for PCB congeners exhibiting dioxin-like toxicity), the magnitude of the risk for shrew exposure to PCBs is high. These results indicate a potential impact on reproduction of mammal insectivore populations such as shrews exposed to PCBs in the diet while foraging in the seasonally ponded and forested/scrub-shrub areas of the Murphy Wetland.

The benthic invertebrate endpoints suggest that there may be impacts from inorganic contaminants on invertebrate communities inhabiting the seasonally ponded area of the Murphy Wetland. The strength of the evidence was based entirely on exceedances of surface water and sediment-effects TRVs.

Overall, the benchmark analysis indicated potential effects on benthic communities from total PCBs and from inorganics, especially chromium, lead, and zinc with the highest HQs attributable

to PCBs, chromium and lead. Since the TRVs used for each of these COPECs was the PEC (probable effect concentration) they represent contaminant levels that potentially eliminate many of the benthic organisms within the community. Surface water concentrations of cyanide, are of concern as this COPEC exceeds its chronic water quality criterion but is less than its acute water quality criterion. Biological effects evaluations, in the form of sediment toxicity testing or benthic community structure were not undertaken for this ERA.

There was evidence of potential risk of impacts on the reproduction or growth of muskrat due to the exposure to PCBs and chromium within the seasonally ponded area of the Murphy Wetland. There was low risk to mallard populations on the Site from exposure to lead. The risk to shrew populations from exposure to PCBs in sediment and surface soil was also present from detected concentrations of PCBs and chromium. However, confidence in these conclusions is low, due to the high uncertainty associated with the estimation of these risks.

5.2 Conclusions

Conclusions for the human health risk assessment and the ecological risk assessment are presented below.

5.2.1 Human Health

The following summarizes RME and CTE exposure scenarios that exceed EPA's target risk range for carcinogens (ILCR of 10^{-6} to 10^{-4}) and risk criterion for noncarcinogens (HI of 1). For these pathways, major risk contributors (ILCRs $>10^{-4}$ or HIs >1, or the contaminant with the greatest cancer risk) are presented. Lead in soil and sediment was evaluated through the use of EPA models for children and adults. The lead evaluation indicated that exposures to lead in current and future soil exposure scenarios would not result in adult or childhood blood lead levels in excess of blood lead level goals. Therefore, lead in soil was determined not to be of concern for human receptors at the Southwest Properties. Lead in groundwater was evaluated by comparing monitoring well concentrations to the Safe Drinking Water Act (SDWA) action level of 15 micrograms per liter (µg/L).

Aberjona Property. The ILCRs and HIs are below risk criteria for all scenarios and pathways evaluated at the Aberjona property.

Whitney Property[10]. The RME and/or CTE ILCR and/or HI exceed the target risk range for the Future Adult/Child Recreational User and Future Construction Worker. The major risk contributors for the Recreational User are direct contact with benzo(a)pyrene and total PCBs in surface soil, and heptachlor, total PCBs and PCB TEQ in subsurface soil. The major risk contributors for Construction Worker exceedances are total PCBs and PCB TEQ in subsurface soil, and cis-1,2-dichloroethene, tetrachloroethene and trichloroethene in shallow groundwater.

Murphy Property. The RME HI exceeds the target risk range for the Future Construction Worker exposed to shallow groundwater and the Future Recreation User exposed to surface and subsurface soil. The major risk contributor for shallow groundwater is cis-1,2-dichloroethene. The major risk contributor for surface and subsurface soil is thallium.

Murphy Wetland. The RME and/or CTE HIs were above the target HI of 1 for the Future Older Child Trespasser and the Future Young Child/Adult Recreational User. The major risk contributors associated with the RME exceedance for the Future Older Child Trespasser is total PCBs in sediment. The major risk contributors for the Future Adult/Child Recreational User are C11-C22 aromatics and total PCBs in sediment for the RME case, and total PCBs for the CTE case. The lead evaluation for sediment indicated that future young child recreational exposures could result in childhood blood lead levels in excess of blood lead level goals. The highest lead concentrations in sediment are located at sampling locations SW-2 (35,100 milligrams per kilogram [mg/kg]), P-12 (24,900 mg/kg), P-14 (16,800 mg/kg), MR-11 (12,000 mg/kg) and P-43 (11,100 mg/kg).

[10] Worker protective measures should be used if excavation work is performed prior to remedy implementation near the rear of the building in the vicinity of the drain line connecting the former Whitney drum storage area to the municipal sewer system. During test pit excavation activities in this area in 2011, odors were observed and workers were outfitted with half-faced respirators with organic vapor cartridges due to elevated VOC readings.

Existing Aberjona Residence.

The ILCRs and HIs are below risk criteria for current and future residents exposed to vapor intrusion pathway VOCs in indoor air at the existing Aberjona residence. Though TCE, PCE and chloroform were not found at significant concentrations for resident exposure in any indoor air samples at the existing Aberjona residence, subslab soil gas concentrations of these compounds are greater than EPA soil gas screening levels for residential properties, with the subslab soil gas concentrations of TCE being the most elevated. The presence of elevated concentrations of VOCs, in particular TCE, in subslab soil gas beneath the existing Aberjona residence indicates a potential for future vapor intrusion to occur if building conditions were to change.

Site-Wide Future Resident. The RME and CTE cancer and non-cancer risks exceed risk management criteria for the future resident exposed to groundwater during household use. The major risk contributors associated with RME exceedances are benzene, 1,1-dichloroethane, cis-1,2-dichloroethene, trans-1,2-dichloroethene, 1,4-dioxane, methylene chloride, tetrachloroethene, 1,2,3-trichlorobenzene, 1,2,4-trichlorobenzene, 1,1,2-trichloroethane, trichloroethene, vinyl chloride, xylenes (total), C5-C8 aliphatics, C9-C12 aliphatics, C9-C10 aromatics, C9-C18 aliphatics, C11-C22 aromatics, 2-methylnaphthalene, naphthalene, PCB TEQ, total PCBs, aldrin, alpha-BHC, lindane, heptachlor, heptachlor epoxide, arsenic, cobalt, iron and manganese. In the CTE case, cis-1,2-dichloroethene, 1,1,2-trichloroethane, 1,2,4-trichlorobenzene, trichloroethene, vinyl chloride, C9-C12 aliphatics, C9-C18 aliphatics, naphthalene, total PCBs, arsenic and manganese were the major risk contributors. In addition, the maximum concentration of lead detected in groundwater (129 µg/L) exceeds the SDWA action level. The elevated lead levels in Murphy Wetland sediment may be related to shallow groundwater concentrations in the vicinity of monitoring wells MW-24, MW-16 and MW-18S which displayed groundwater lead concentrations of 129 µg/L, 36.2 µg/L and 16.8 µg/L, respectively, in 2011. These monitoring wells are located within or adjacent to the Murphy Wetland.

Background surface and subsurface soil data for arsenic were compared to the soil data for the Whitney property where arsenic was identified as a risk contributor. The comparison indicates that the concentrations of arsenic in surface soils at the Whitney property are comparable to the background surface soil concentrations. However, arsenic in subsurface soil at the Whitney

property were substantially greater than those in background subsurface soil. Thus, background conditions contribute to the calculated site-related risks associated with exposure to surface soil arsenic at the Whitney property. Significantly elevated concentrations of arsenic in subsurface soil at the Whitney property were located at sampling location WB-201 (110 mg/kg at 3-5' and 140 mg/kg at 5-6'). Other Whitney property subsurface soil sampling locations had concentrations within the range of background concentrations or slightly greater than the background range. Site-wide groundwater COPCs concentrations were consistently greater than concentrations detected in the background wells.

Background surface and subsurface soil data for thallium were compared to soil data for the Murphy property where thallium was identified as a risk contributor. Thallium was not detected in background soils with reporting limits ranging from 0.14 mg/kg to 0.16 mg/kg. Thallium was detected in surface soil at concentrations ranging from 0.054 mg/kg to 10 mg/kg, and in subsurface soil from 0.069 mg/kg to 30 mg/kg. Five locations (one surface soil location; 4 subsurface soil locations) have thallium concentrations above the non-detect background levels identified for soil (B-18 [0-2'], B-10 [6-10' and 10-14'], B-5 [13-15'], B-8 [7-8' and 8-12'] and B-9 [6-10']). Therefore, it appears that thallium at these Murphy property surface and subsurface locations are not associated with background conditions at the site.

Should a change in land use at the Southwest Properties be contemplated that would include activities and uses not evaluated in the risk assessment, further evaluation will be required to assess the risks associated with the proposed land use change, including use of groundwater for purposes not identified in the risk assessment. In addition, the future vapor intrusion pathway will require further evaluation if a change in usage of any of the existing commercial buildings is contemplated that would result in higher occupancy (e.g., full-time commercial use of the Whitney or Murphy buildings or daycare use of the Aberjona building), or as part of new building construction including any addition to existing buildings on any of the properties. Use of a vapor barrier or subslab system may be appropriate to mitigate the vapor intrusion pathway in instances of future development/construction of occupied buildings.

5.2.2 Ecological Risk Assessment

The sediment benchmark analysis indicated potential effects on benthic communities from total PCBs and from inorganics, especially chromium, lead, and zinc with the highest HQs attributable to PCBs, chromium and lead. Since the TRVs used for each of these COPECs were the PECs (probable effect concentrations), they represent contaminant levels that potentially eliminate many of the benthic organisms within the community. Surface water concentrations of cyanide, are of concern as this COPEC exceeds its chronic water quality criterion but is less than its acute water quality criterion. Biological effects evaluations, in the form of sediment toxicity testing or benthic community structure were not undertaken for this ERA.

There was evidence of potential risk of impacts on the reproduction of muskrat due to the exposure to PCBs and chromium within the seasonally ponded area of the Murphy Wetland. There was low risk to mallard populations on the Site from exposure to lead. The risk to shrew populations from exposure to PCBs in sediment and surface soil was also present from detected concentrations of PCBs and chromium. However, confidence in these conclusions is low, due to the high uncertainty associated with the estimation of these risks.

The following table summarizes the sediment and surface soil risk contributors for the Murphy Wetland. A summary of the risk contributors for ecological receptors inhabiting the Murphy Wetland is also presented in Figure 5-2.

Summary of Ecological Receptor Risks for Murphy Wetland

Receptor	Receptor Indicator Species	Habitat	Major Contributors to Risk*
Macrobenthic Community	Not Applicable	Seasonally Ponded Area	PCB Aroclors 1254/1260** chromium lead zinc
Mammalian Herbivore	Muskrat	Seasonally Ponded Area	Dioxin-like PCB congeners** PCB Aroclors 1254/1260** chromium

Summary of Ecological Receptor Risks for Murphy Wetland			
Receptor	**Receptor Indicator Species**	**Habitat**	**Major Contributors to Risk***
Mammalian Insectivore	Short-tailed Shrew	Seasonally Ponded Area	Dioxin-like PCB congeners** PCB Aroclors 1254/1260** Chromium
		Forested/Scrub-Shrub Area	PCB Aroclor 1254**' Chromium

Notes:
* - HQ > 1 for LOAEL or PEC/SEL
** - Greatest risk contributor for that receptor.
NA – Not applicable
HQ – Hazard Quotient
LOAEL – Lowest Observable Adverse Effect Level
PEC/SEL – Probable Effect Concentration and Severe Effect Level (Sediment Benchmarks)
PCB – polychlorinated biphenyls

Woburn, Massachusetts

Exposure Point	Scenario/ Receptor	Exposure Media	RME or CT	Total Cancer Risks	Total Noncancer Risks	Media > 1E-04 or HI > 1	Primary contributors to risk (> 1E-06, HI > 1)
Site Wide	Future Young Child/Adult Off-site Resident	tap water	RME	**3E-01**	**3E+03**	tap water	(C) - benzene, 1,4-dichlorobenzene, 1,1-dichloroethane, 1,2-dichloroethane, 1,4-dioxane, 1,1,2-trichloroethane, ethylbenzene, methyl tert-butyl ether, methylene chloride, tetrachloroethene, 1,2,4-trichlorobenzene, trichloroethene, vinyl chloride, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, naphthalene, indeno(1,2,3-cd)pyrene, PCB TEQ, total PCBs, 4,4'-DDD, 4,4'-DDT, aldrin, alpha-BHC, alpha-chlordane, beta-BHC, dieldrin, lindane, gamma-chlordane, heptachlor, heptachlor epoxide, arsenic; (NC) - benzene, cis-1,2-dichloroethene, trans-1,2-dichloroethene, methylene chloride, tetrachloroethene, 1,2,3-trichlorobenzene, 1,2,4-trichlorobenzene, 1,1,2-trichloroethane, trichloroethene, vinyl chloride, xylenes (total), C5-C8 aliphatics, C9-C12 aliphatics, C9-C10 aromatics, C9-C18 aliphatics, C11-C22 aromatics, 2-methylnaphthalene, naphthalene, PCB TEQ, total PCBs, aldrin, lindane, heptachlor epoxide, arsenic, cobalt, iron, lead+, manganese
			CTE	**6E-03**	**9E+01**		

Notes

Bolded values exceed a cancer risk of 1E-04 or a target organ HI of 1.

HI - Hazard Index
RME - Reasonable Maximum Exposure
CTE - Central Tendency Exposure

* Based on childhood lead model for sediment.
\+ Based on exceedance of Safe Drinking Water Act Action Level for groundwater
(C) - Carcinogenic Risk
(NC) - Noncarcinogenic Risk
NE - Not Evaluated
N/A - Not Applicable

Executive Summary

City of Woburn, 2012. Zoning Map of the City of Woburn. October 2012.

Clean Harbors, 1996. *Corrective Action Investigation Report*, Volumes 1, 2, and 3. Murphy's Waste Oil Service, Inc., 252 Salem Street, Woburn, Massachusetts, April 15, 1996.

Clean Harbors, 1998. *Corrective Action Investigation Report (Part II)*, Volume I of I, Murphy's Waste Oil Sources, Inc., Woburn, Massachusetts, 1998.

Massachusetts Department of Environmental Protection (MassDEP). 2004. Letter: *Groundwater Use and Value Determination, Wells G&H Superfund Site, Massachusetts*. Richard Chalpin, Assistant Commissioner, Bureau of Waste Site Clean-up, MassDEP to Robert Cianciarulo, Chief, Massachusetts Superfund Section, EPA, June 21, 2004.

RETEC, 1994. *Draft Remedial Investigation Southwest Properties, Wells G&H Site, Woburn, Massachusetts*, Prepared for Beatrice Company. Prepared by Remediation Technologies, Inc, Concord Massachusetts, February, 1994.

RETEC, 2003. *Supplemental Remedial Investigation Report, Southwest Properties, Volumes 1 through XXIII, Wells G&H Superfund Site, Woburn, Massachusetts*. Prepared for: Beatrice Company, Prepared by: The RETEC Group, Inc., Concord, Massachusetts, August 2003.

TRC, 2004. *EPA/TRC and RETEC Split Sample Comparison Report for the Wells G&H Southwest Properties Supplemental Remedial Investigation.* Prepared by TRC Environmental Corporation, Lowell, Massachusetts. February 2004.

U.S. Environmental Protection Agency (EPA). 1989. *Risk Assessment Guidance for Superfund. Volume I: Human Health Evaluation Manual. Part A.* Interim Final. EPA/540/1-89/002. December 1989.

U.S. Environmental Protection Agency (EPA). 1992. *Supplemental Guidance to RAGS: Calculating the Concentration Term.* Office of Solid Waste and Emergency Response. Washington, D.C. Publication 9285.7-081. May 1992.

U.S. Environmental Protection Agency (EPA). 2004. *Baseline Human Health and Ecological Risk Assessment Report, Wells G&H Superfund Site, Aberjona River Study, Operable Unit 3, Woburn, Massachusetts*. Prepared by Metcalf & Eddy, Inc., Wakefield, Massachusetts. September 2004.

U.S. Environmental Protection Agency (EPA). 2005. *Draft Final MSGRP Remedial Investigation Report, Industri-Plex Superfund Site, Operable Unit 2, Woburn, Massachusetts,* Prepared by Tetra Tech NUS Inc., Wilmington, Massachusetts. March 2005.

U.S. Environmental Protection Agency (EPA). 2011. *ProUCL Version 4.1 for Environmental Applications for Data Sets with and without Nondetect Observations.* Prepared for EPA by Lockheed Martin Environmental Services. March 2011.

U.S. Environmental Protection Agency (EPA). 2013. *ProUCL Version 5.0.00 for Environmental Applications for Data Sets with and without Nondetect Observations.* Prepared for EPA by Lockheed Martin Environmental Services. September 2013.

SECTION 3 TABLES

TABLE 3-1
SELECTION OF EXPOSURE PATHWAYS
Southwest Properties, Wells G&H Superfund Sites
Operable Unit 2
Woburn, Massachusetts

Scenario Timeframe	Medium	Exposure Medium	Exposure Point	Receptor Population	Receptor Age	Exposure Route	Type of Analysis	Rationale for Selection or Exclusion of Exposure Pathway
Current	Soil	Surface Soil (0 - 2 feet)	Aberjona, Whitney and Murphy Properties	Commercial Worker	Adult	Ingestion Inhalation Dermal	Quant Qual Quant	Commercial workers are currently present on-Site. Inhalation expected to be negligable Commercial workers are currently present on-Site.
			Aberjona Property	Ice Skating Rink User	Adult/Child	Ingestion Inhalation Dermal	None None None	Due to pavement in this area of the property, current soil exposure pathways are incomplete. Due to pavement in this area of the property, current soil exposure pathways are incomplete. Due to pavement in this area of the property, current soil exposure pathways are incomplete.
			Whitney Property	Trespasser	Older Child	Ingestion Inhalation Dermal	Quant Qual Quant	Open gates render this area accessible. Inhalation expected to be negligable Open gates render this area accessible.
	Subslab Soil Gas	Indoor Air	Aberjona, Whitney and Murphy Properties	Commercial Worker	Adult	Inhalation	Qual	Concentrations of VOCs in soil gas at the Aberjona and Murphy properties are not expected to significantly impact indoor air. Whitney building primarily used for storage.
	Air	Indoor Air	Existing Aberjona Residence *	Resident	Adult	Inhalation	Quant	Volatile compounds present in shallow groundwater may impact indoor air at residence via migration through subslab soil gas.
					Child	Inhalation	Quant	Volatile compounds present in shallow groundwater may impact indoor air at residence via migration through subslab soil gas.
	Groundwater	Groundwater	Site-Wide	Resident	Adult	Ingestion Inhalation Dermal	None None None	No known potable use of on-Site groundwater. No known potable use of on-Site groundwater. No known potable use of on-Site groundwater.
					Young	Ingestion Inhalation Dermal	None None None	No known potable use of on-Site groundwater. No known potable use of on-Site groundwater. No known potable use of on-Site groundwater.
	Surface Water	Surface Water	Murphy Wetland	Trespasser	Older Child	Ingestion Dermal	None Quant	Access is limited at these Sites due to fencing, but access may be gained via open gate at Whitney. Access is limited at these Sites due to fencing, but access may be gained via open gate at Whitney.
	Sediment	Sediment	Murphy Wetland	Trespasser	Older Child	Ingestion Dermal	Quant Quant	Access is limited at these Sites due to fencing, but access may be gained via open gate at Whitney. Access is limited at these Sites due to fencing, but access may be gained via open gate at Whitney.
Future	Soil	Surface Soil (0 - 2 feet)	Aberjona, Whitney and Murphy Properties	Commercial Worker	Adult	Ingestion Inhalation Dermal	Quant Qual Quant	Commercial workers may continue to work On-Site in the future. Exposure to fugitive dust expected to be negligible. Commercial workers may continue to work On-Site in the future.
				Trespasser	Older Child	Ingestion Inhalation Dermal	Quant Qual Quant	Site access in the future may not be restricted. Exposure to fugitive dust expected to be negligible. Site access in the future may not be restricted.
				Recreational User	Adult	Ingestion Inhalation Dermal	Quant Qual Quant	Future Site plans may include recreational use. Exposure to fugitive dust expected to be negligible. Future Site plans may include recreational use.
					Young	Ingestion Inhalation Dermal	Quant Qual Quant	Future Site plans may include recreational use. Exposure to fugitive dust expected to be negligible. Future Site plans may include recreational use.
				Construction Worker	Adult	Ingestion Inhalation Dermal	Quant Quant Quant	Future site plans may involve construction. Construction workers may come into contact with contaminated soil. Future site plans may involve construction. Construction workers may come into contact with contaminated fugitive dusts. Future site plans may involve construction. Construction workers may come into contact with contaminated soil.
		Subsurface Soil (2 - 15 ft)	Aberjona, Whitney and Murphy Properties	Recreational User	Adult	Ingestion Inhalation Dermal	Quant Qual Quant	Future Site plans may include recreational use. Exposure to fugitive dust expected to be negligible. Future Site plans may include recreational use.
					Young	Ingestion Inhalation Dermal	Quant Qual Quant	Future Site plans may include recreational use. Exposure to fugitive dust expected to be negligible. Future Site plans may include recreational use.
				Construction Worker	Adult	Ingestion Inhalation Dermal	Quant Quant Quant	Future site plans may involve construction. Construction workers may come into contact with contaminated soil. Future site plans may involve construction. Construction workers may come into contact with contaminated fugitive dusts. Future site plans may involve construction. Construction workers may come into contact with contaminated soil.
		Outdoor Air	Aberjona, Whitney and Murphy Properties	Construction Worker	Adult	Inhalation	Quant	Future Site plans will likely involve construction. Construction workers may be exposed to fugitive contaminant vapors attributable to contaminated soil that migrate to the air space of construction excavations.

* Existing Aberjona Residence yard previously evaluated as part of Wells G&H OU-3 River Study (EPA, 2004a).

TABLE 3-1
SELECTION OF EXPOSURE PATHWAYS
Southwest Properties, Wells G&H Superfund Sites
Operable Unit 2
Woburn, Massachusetts

Scenario Timeframe	Medium	Exposure Medium	Exposure Point	Receptor Population	Receptor Age	Exposure Route	Type of Analysis	Rationale for Selection or Exclusion of Exposure Pathway
Future (cont.)	Subslab Soil Gas	Indoor Air	Aberjona, Whitney and Murphy Properties	Commercial Worker	Adult	Inhalation	None	Vapor intrusion pathway will require further evaluation and/or mitigation if a future building is constructed at any of the properties.
				Recreational User	Adult	Inhalation	None	Vapor intrusion pathway will require further evaluation and/or mitigation if a future building is constructed at any of the properties.
					Young Child	Inhalation	None	Vapor intrusion pathway will require further evaluation and/or mitigation if a future building is constructed at any of the properties.
	Air	Indoor Air	Existing Aberjona Residence	Resident	Adult	Inhalation	Quant	Volatile compounds present in shallow groundwater may impact indoor air at residence via migration through subslab soil gas.
					Child	Inhalation	Quant	Volatile compounds present in shallow groundwater may impact indoor air at residence via migration through subslab soil gas.
	Groundwater	Groundwater	Site-Wide	Resident	Adult	Ingestion Inhalation Dermal	Quant Quant Quant	Site groundwater could be used as a future drinking water source. Residents may be exposed to VOCs present in Site groundwater during showering. Future residents could experience dermal exposure to contaminants in Site groundwater while showering.
					Young	Ingestion Inhalation Dermal	Quant Quant Quant	Site groundwater could be used as a future drinking water source. Residents may be exposed to VOCs present in Site groundwater during showering. Future residents could experience dermal exposure to contaminants in Site groundwater while showering.
		Shallow Groundwater	Aberjona, Whitney and Murphy Properties	Construction Worker	Adult	Ingestion Dermal	Quant Quant	Construction workers may come into contact with contaminated groundwater during excavation dewatering and other construction activities. Construction workers may come into contact with contaminated groundwater during excavation dewatering and other construction activities.
		Outdoor Air	Aberjona, Whitney, and Murphy Properties	Construction Worker	Adult	Inhalation	Quant	Future Site plans include possible recreational use which will involve construction. Construction workers may be exposed to VOCs in Site groundwater that migrate to the air space of
	Surface	Surface Water	Murphy Wetland	Recreational User	Adult	Ingestion Dermal	None Quant	Wading Scenario: Ingestion is unlikely during wading Standing water has been observed in the Murphy wetland. Contaminants in sediments could partition to aqueous phases.
					Young	Ingestion Dermal	None Quant	Wading Scenario: Ingestion is unlikely during wading Standing water has been observed in the Murphy wetland. Contaminants in sediments could partition to aqueous phases.
				Trespasser	Older Child	Ingestion Dermal	None Quant	Wading Scenario: Ingestion is unlikely during wading Standing water has been observed in the Murphy wetland. Contaminants in sediments could partition to aqueous phases.
	Sediment	Sediment	Murphy Wetland	Recreational User	Adult	Ingestion Dermal	Quant Quant	Contaminated sediments have been identified in the Murphy property wetlands. Contaminated sediments have been identified in the Murphy property wetlands.
					Young	Ingestion Dermal	Quant Quant	Contaminated sediments have been identified in the Murphy property wetlands. Contaminated sediments have been identified in the Murphy property wetlands.
				Trespasser	Older Child	Ingestion Dermal	Quant Quant	Contaminated sediments have been identified in the Murphy property wetlands. Contaminated sediments have been identified in the Murphy property wetlands.

(1) Minimum/maximum detected concentration.
(2) Maximum concentration used for screening.
(3) Refer to supporting information for background discussion.
(4) USEPA Region 9 RSLs for residential soil (adjusted to an hazard quotient = 0.1 for noncarcinogens), November 2013.
RSL for chromium III used for total chromium.
RSL for chromium VI used for chromium VI.
RSL for mercuric chloride used for mercury.
RSL for free cyanide used for total cyanide.
RSL of cyclohexane used for methyl cyclohexane.
RSL for diethylphthalate used for dimethylphthalate.
RSL for pyrene used for acenaphthylene, benzo(g,h,i)perylene and phenanthrene.
RSL for chlordane used for alpha- and gamma-chlordane.
RSL for alpha-BHC used for delta-BHC.
RSL for endosulfan used for endosulfan II and endosulfan sulfate.
RSL for endrin used for endrin aldehyde.
RSL for 1,4-dichlorobenzene used for 1,3-dichlorobenzene.
RSL for VPH/EPH fractions calculated using on-line RSL calculator and PPRTVs.
The screening toxicity value for lead is the residential soil lead guidance level of 400 mg/Kg (USEPA, 1994a).

(5) Rationale Codes:
Selection Reason: Above Screening Levels (ASL)
No Toxicity Information (NTX)
Deletion Reason: Essential Nutrient (NUT)
Below Screening Level (BSL)

Definitions:
mg/kg = milligams per kilogram
COPCs = Chemicals of Potential Concern
ARAR/TBC = Applicable or Relevant and Appropriate Requirement/To Be Considered
RSL = Regional Screening Level
J = Estimated Value
C = Carcinogenic
N = Non-Carcinogenic
N/A = Not Applicable or Not Available
ND = Not Detected
EB = Blank contamination

VOCs - Volatile Organic Compounds.
VPH - Volatile Petroleum Hydrocarbons.
EPH - Extractable Petroleum Hydrocarbons.
SVOCs - Semivolatile Organic Compounds.
PCBs - Polychlorinated Biphenyls.
TEQ - Toxicity Equivalent; calculated using 2005 WHO Toxicity Equivalent Factors and half detection limits for non-detects.

TABLE 3-2.1.1
OCCURRENCE, DISTRIBUTION AND SELECTION OF CHEMICALS OF POTENTIAL CONCERN
Southwest Properties, Wells G&H Superfund Site Operable Unit 2 Woburn, Massachusetts

Scenario Timeframe: Current
Medium: Soil
Exposure Medium: Surface Soil

Exposure Point	CAS Number	Chemical	Minimum Concentration (Qualifier) (1)		Maximum Concentration (Qualifier) (1)		Units	Location of Maximum Concentration	Detection Frequency	Range of Detection Limits

Notes:

(1) Minimum/maximum detected concentration.

J - Estimated value.

mg/kg - milligams per kilogram

ND - Not detected.

VOCs - Volatile Organic Compounds.

VPH - Volatile Petroleum Hydrocarbons.

EPH - Extractable Petroleum Hydrocarbons.

SVOCs - Semivolatile Organic Compounds.

PCBs - Polychlorinated Biphenyls.

TEQ - Toxicity Equivalent; calculated using 2005 WHO Toxicity Equivalent Factors and half detection limits for non-detects.

(a) Data presented are from soil samples AB-15/0-2, AB-16/0-2, AB16SS(0-2.0), AB-SS5, AB-SS6, AB-SS7, AB-SS8, AB-SS9, AB-14/0-2, AB14SS(0-2.0), AB15SS(0-2.0), AB 208 (0-2)-A-1, AB 209 (0-2)-A-1, AB 210 (0-2)-A-1, AB 211 (0-2)-A-1

(b) Data presented are from soil samples WB-6/0-2, WB6SS(0-2.0), WB-7/0-2, WB7SS(0-2.0), WB-10/0-2, WB10SS(0-2.0), WB-11/1-1.75, WB11SS(0-1.0), WB12SS(1.0-2.0), WB-13/0-2, WB13SS(0-2.0), WB-SS1, WB-SS2, WB-SS3, WB-8/0-2, WB8SS(0-1.0), WB-SS4, WB201(0-2)-W, WB202(0-2)-W, WB203(0-2)-W, WB-203(0-2)-W-120110-1, WB213(0-2)-W-1, WB214(0-2)-W, WB215(0-2)-W, WB216(0-2)-W, WB217(0-2)-W, WB 218 (0-2)-W-1, WB 219 (0-2)-W-1, WB 220 (0-2)-W-1, WB302 (0-2)-W-1, WB303 (0-2)-W-1, WB308 (0-2)-W-1, WB313 (0-2)-W-122110-1.

Notes:

(1) Minimum/maximum detected concentration.

J - Estimated value.

mg/kg - milligams per kilogram

VOCs - Volatile Organic Compounds.

VPH - Volatile Petroleum Hydrocarbons.

EPH - Extractable Petroleum Hydrocarbons.

SVOCs - Semivolatile Organic Compounds.

PCBs - Polychlorinated Biphenyls.

TEQ - Toxicity Equivalent; calculated using 2005 WHO Toxicity Equivalent Factors and half detection limits for non-detects.

(a) Data presented are from soil samples AB-15/0-2, AB-16/0-2, AB16SS(0-2.0), AB-SS1, AB-SS2, AB-SS3, AB-SS4, AB-SS5, AB-SS6, AB-SS7, AB-SS8, AB-SS9, AB-14/0-2, AB14SS(0-2.0), AB15SS(0-2.0), AB-13/0-2, AB13SS(0-2.0), AB201 (0-2)-A-1, AB202 (0-2)-A-1, AB203 (0-2)-A-1, AB 204 (0-2)-A-1, AB205 (0-2)-A-1, AB206 (0-2)-A-1, AB207 (0-2)-A-1, AB 208 (0-2)-A-1, AB 209 (0-2)-A-1, AB 210 (0-2)-A-1, AB 211 (0-2)-A-1, AB 212 (0-2)-A-1, AB 213 (0-2)-A-1, AB 214 (0-2)-A-1.

TABLE 3-2.1.3
OCCURRENCE, DISTRIBUTION AND SELECTION OF CHEMICALS OF POTENTIAL CONCERN
Southwest Properties, Wells G&H Superfund Site Operable Unit 2 Woburn, Massachusett

Scenario Timeframe: Future
Medium: Soil
Exposure Medium: Subsurface Soil

Exposure Point	CAS Number	Chemical	Minimum Concentration (Qualifier) (1)	Maximum Concentration (Qualifier) (1)	Units	Location of Maximum Concentration	Detection Frequency	Range of Detection Limits

Notes:

(1) Minimum/maximum detected concentration.

J - Estimated value.

mg/kg - milligams per kilogram

VOCs - Volatile Organic Compounds.

VPH - Volatile Petroleum Hydrocarbons.

EPH - Extractable Petroleum Hydrocarbons.

SVOCs - Semivolatile Organic Compounds.

PCBs - Polychlorinated Biphenyls.

TEQ - Toxicity Equivalent; calculated using 2005 WHO Toxicity Equivalent Factors and half detection limits for non-detects.

(a) Data presented are from soil samples AB-15/4-4.5, AB-SS1D, AB-SS2D, AB-SS3D, AB-SS4D, AB-SS5D, AB-SS6D, AB-SS7D, AB-SS8D, AB-SS9D, AB14D(2.0-4.0), AB15D(4.0-4.5), AB13D(5.0-7.0), AB-13/5-7, AB102(6.0), AB201 (4-5)-A-1, AB201 (5-7)-A-1, AB202 (4-6)-A-1, AB202 (10-12)-A-1, AB203 (4-6)-A-1, AB203 (6-8)-A-1, AB 204 (5-7)-A-1, AB 204 (7-10)-A-1, AB205 (4-6)-A-1, AB205 (6-8)-A-1, AB206 (6-8)-A-1, AB206 (13-15)-A-1, AB207 (4-6)-A-1, AB207 (6-8)-A-1, AB 208 (3-5)-A-1, AB 208 (5-7)-A-1, AB 209 (5-7)-A-1, AB 209 (10-12)-A-1, AB 210 (2-5)-A-1, AB 210 (5-7)-A-1, AB 211 (3-5)-A-1, AB 211 (5-7)-A-1, AB 212 (5-7)-A-1, AB 212 (7-10)-A-1, AB 213 (3-5)-A-1, AB 213 (5-7)-A-1, AB 214 (8-10)-A-1, AB 214 (11-12)-A-1, AB 214 (11-13)-A-1.

(b) Data presented are from soil samples WB-6/2-4, WB6D(2.0-4.0), WB-7/2-4, WB7D(2.0-4.0), WB-10/2-4, WB10D(2.0-4.0), WB-SS1D, WB-SS2D, WB-SS3D, WB-SS4D, WB201(3-5)-W, WB-201(4-5)-W, WB201(5-6)-W, WB202(2.5-4.5)-W, WB202(5-7)-W, WB203(3-5)-W, WB-203(3-5)-W-120110-1, WB203(5-7)-W, WB-203(5-7)-W-120110-1, WB205(2-4)-W, WB205(4-5)-W, WB205(4-5)-W-1, WB206(4-5)-W, WB206(5-6)-W, WB207(4-5)-W, WB207(10-12)-W, WB209(4-5)-W, WB209(10-12)-W, WB211(4-5)-W, WB211(10-12)-W, WB213(5-7)-W-1, WB213(8-10)-W-1, WB214(2-4)-W, WB214(5-7)-W, WB215(4-5)-W, WB215(10-12)-W, WB216 (3-5)-W, WB216(4-5)-W, WB216(10-12)-W, WB217(5-7)-W, WB217(10-12)-W, WB 218 (4-5)-W-1, WB 218 (5-7)-W-1, WB 219 (4.5-6.5)-W-1, WB 219 (10-12)-W-1, WB 220 (4.5-5.5)-W-1, WB 220 (5.5-7.5)-W-1, WB302 (6-9)-W-1, WB302 (10-12)-W-1, WB303 (4-5)-W-1, WB303 (10-12)-W-1, WB303 (12-15)-W-1, WB308 (3-5)-W-1, WB308 (13-15)-W-1, WB313 (3-5)-W-122110-1, WB313 (5-7)-W-122110-1, WTP204(4-4.5)-W-120210-1, WTP204(5-5.5)-W-120210-1, WTP-204BL12(7-7.5), WTP-204BL5(4.5-5), WTP-204BL7(4.5-5), WTP-204BL9(6-7)-W.

(1) Minimum/maximum detected concentration.
(2) Maximum concentration used for screening.
(3) Refer to supporting information for background discussion.
(4) USEPA Region 9 RSLs for Tapwater (adjusted to an hazard quotient = 0.1 for noncarcinogens), November 2013.
RSL for chromium III used for total chromium.
RSL for chromium VI used for chromium VI.
RSL for mercuric chloride used for mercury.
RSL for free cyanide used for total cyanide.
RSL of cyclohexane used for methyl cyclohexane.
RSL for 1,4-dichlorobenzene used for 1,3-dichlorobenzene.
RSL for diethylphthalate used for dimethylphthalate.
RSL for pyrene used for acenaphthylene, benzo(g,h,i)perylene and phenanthrene.
RSL for chlordane used for alpha- and gamma-chlordane.
RSL for alpha-BHC used for delta-BHC.
RSL for endosulfan used for endosulfan II and endosulfan sulfate.
RSL for endrin used for endrin aldehyde.
RSL for VPH/EPH fractions calculated using on-line RSL calculaotr and PPRTVs.
The screening toxicity value for lead is the residential soil lead guidance level of 400 mg/Kg (USEPA, 1994a).

(5) Rationale Cod Above Screening Levels (ASL)
Selection Reason No Toxicity Information (NTX)
Deletion Reason: Essential Nutrient (NUT)
Below Screening Level (BSL)

Definitions:
mg/kg = milligams per kilogram
COPCs = Chemicals of Potential Concern
ARAR/TBC = Applicable or Relevant and Appropriate Requirement/To Be Considered
RSL = Regional Screening Level
J = Estimated Value
C = Carcinogenic
N = Non-Carcinogenic
N/A = Not Applicable or Not Available
ND = Not Detected
VOCs - Volatile Organic Compounds.
VPH - Volatile Petroleum Hydrocarbons.
EPH - Extractable Petroleum Hydrocarbons.
SVOCs - Semivolatile Organic Compounds.
PCBs - Polychlorinated Biphenyls.
TEQ - Toxicity Equivalent; calculated using 2005 WHO Toxicity Equivalent Factors and half detection limits for non-detects.

	7440-62-2	Vanadium	1.07E+01		1.07E+01		ug/L	S77-D	1/6	5.0 - 5.5

Notes:

(1) Minimum/maximum detected concentration.

J - Estimated value.

ug/L - micrograms per liter.

ND - Not detected.

VOCs - Volatile Organic Compounds.

VPH - Volatile Petroleum Hydrocarbons.

EPH - Extractable Petroleum Hydrocarbons.

SVOCs - Semivolatile Organic Compounds.

PCBs - Polychlorinated Biphenyls.

TEQ - Toxicity Equivalent; calculated using 2005 WHO Toxicity Equivalent Factors and half detection limits for non-detects.

Notes:

(1) Minimum/maximum detected concentration.

J - Estimated value.

ND - Not detected.

ug/L - micrograms per liter.

ND - Not detected.

VOCs - Volatile Organic Compounds.

VPH - Volatile Petroleum Hydrocarbons.

EPH - Extractable Petroleum Hydrocarbons.

SVOCs - Semivolatile Organic Compounds.

PCBs - Polychlorinated Biphenyls.

TEQ - Toxicity Equivalent; calculated using 2005 WHO Toxicity Equivalent Factors and half detection limits for non-detects.

) Data presented are from surface water samples BW4SW,MW12SW,MW13SW

) Minimum/maximum detected concentration.
) Maximum concentration used for screening.
) Refer to supporting information for background discussion.
) USEPA Region 9 RSLs for tap water (adjusted to an hazard quotient = 0.1 for noncarcinogens), November 2013.
RSL for chromium VI used for total chromium.
RSL for mercury and compounds used for mercury.
RSL for free cyanide used for total cyanide.
) Rationale Codes:
election Reason: Above Screening Levels (ASL)
eletion Reason: No Toxicity Information (NTX)
Essential Nutrient (NUT)
Below Screening Level (BSL)

Definitions:
ug/L = micrograms per liter
CAS = Chemical Abstract Service
COPCs = Chemicals of Potential Concern
ARAR/TBC = Applicable or Relevant and Appropriate Requirement/To Be Considered
RSL = Regional Screening Level
N/A = Not Applicable or Not Available
ND = Not Detected
J = Estimated Value
C = Carcinogenic
N = Non-Carcinogenic
MCL = Maximum Contaminant Level
EPA = Environmental Protection Agency

(1) Minimum/maximum detected concentration.
(2) Maximum concentration used for screening.
(3) Refer to supporting information for background discussion.
(4) USEPA Region 9 RSLs for residential soil (adjusted to an hazard quotient = 0.1 for noncarcinogens), November 2013.
RSL for chromium III used for total chromium.
RSL for chromium VI used for chromium VI.
RSL for methyl mercury used for mercury.
RSL for free cyanide used for total cyanide.
RSL for cyclohexane used for methyl cyclohaxane.
RSL for diethylphthalate used for dimethyl phthalate.
RSL flr pyrene used for acenaphthylene, benzo(g,h,i)perylene and phenanthrene.
RSL for chlordane used for alpha- and gamma-chlordane.
RSL for endrin used for endrin aldehyde.
RSL for VPH/EPH fractions calculated for online calculator and PPRTVs.
The screening toxicity value for lead is the residential soil lead guidance level of 400 mg/Kg (USEPA, 1994a).
(5) Rationale Codes:
Selection Reason: Above Screening Levels (ASL)
Deletion Reason: No Toxicity Information (NTX)
Essential Nutrient (NUT)
Below Screening Level (BSL)

TEQ - Toxicity Equivalent; calculated using 2005 WHO Toxicity Equivalent Factors and half detection limits for non-detects.

Definitions:
mg/kg = milligams per kilogram
COPCs = Chemicals of Potential Concern
ARAR/TBC = Applicable or Relevant and Appropriate Requirement/To Be Considered
RSL = Regional Screening Level
J = Estimated Value
C = Carcinogenic
N = Non-Carcinogenic
N/A = Not Applicable or Not Available
ND = Not Detected

TABLE 3-2.5
OCCURRENCE, DISTRIBUTION AND SELECTION OF CHEMICALS OF POTENTIAL CONCERN
Southwest Properties, Wells G&H Superfund Site Operable Unit 2 Woburn, Massachusett

Scenario Timeframe: Future
Medium: Soil (0-15ft) + Groundwater
Exposure Medium: Outdoor Air

Exposure Point (e)	CAS Number	Chemical (b)	Minimum Concentration (Qualifier) (1)	Maximum Concentration (Qualifier) (1)	Units	Location of Maximum Concentration	Detection Frequency	Range of Detectionn Limits	Concentration Used for Screening (2)	Background Value (3)	Screening Toxicity Value (N/C) (4)	Potential ARAR/TBC Value	Potential ARAR/TBC Source	COPC Flag (Y/N)	Rationale for Selection or Deletion (5)
Murphy Property (c,d)	71-55-6	1,1,1-Trichloroethane	N/A	4.80E-02	ug/m3	N/A	N/A	N/A	4.80E-02	N/A	2.20E+03 N	N/A	N/A	N	BSL

(e) Compounds listed are limited to those with a Henry's Law Constant greater than 1X10^{-5} atm-m^3/mole and a molecular weight less than 200 grams/mole

(1) Minimum/maximum detected concentration.
(2) Maximum concentration used for screening.
(3) Refer to supporting information for background discussion.
(4) USEPA Region 9 RSLs for industrial air (adjusted to an hazard quotient = 0.1 for noncarcinogens), November 2013.
RSL of cyclohexane used for methyl cyclohexane.
RSL of 1,2,4-trichlorobenzene used for 1,2,3-trichlorobenzene.
RSL of 1,4-dichlorobenzene used for 1,3-dichlorobenzene.
RSL of 1,2,4-trimethylbenzene used for 1,3,5-trimethylbenzene.
RSL of naphthalene used for acenaphthylene, acenaphthene, anthracene, fluorene, phenanthrene, pyrene and 2-methylnaphthalene.
RSL of isopropylbenzene used for p-isopropyltoluene, n-butyl benzene and sec-butyl benzene.
RSL of cis-1,2-dichloroethene used for trans-1,2-dichloroethene and 1,2-dichloroethene.
(5) Rationale Codes:
Selection Reason: Above Screening Level (ASL)
No Screening Level (NSL)
Deletion Reason Below Screening Level (BSL
No Toxicity Information (NTX

Definitions: ug/m^2 = micrograms per cubic mete
ARAR/TBC = Applicable or Relevant and Appropriate Requirement/To Be Considered
N/A = Not Applicable or Not Available
C = Carcinogenic
N = Non-Carcinogenic

Notes:

(a) Data presented are from soil samples AVP203-A-111710-1, AVP204-A-111710-1, AVP205-A-111710-1 and AVP206-A-111710-1.

(b) Data presented are from soil gas samples WVP205-W-111710-1, WVP206-W-111710-1, WVP206-W-111710-1 Dup, WVP207-W-111710-1, WVP207-W-111710-1, WVP209-W-111710-1 and WVP211-W-111710-1.

(c) Data presented are from soil gas sample MVP206-M-111710-1.

(1) Minimum/maximum detected concentration.
(2) Maximum concentration used for screening.
(3) Refer to supporting information for background discussion.
(4) Soil Gas Screening Level (10 times USEPA Region 9 RSLs for Industrial Air; adjusted to an hazard quotient = 0.1 for noncarcinogens), November 2013.
SGSL for chromium III used for total chromium.
SGSL for chromium VI used for chromium VI.
SGSL for mercuric chloride used for mercury.
SGSL for free cyanide used for total cyanide.
SGSL for cyclohexane used for methyl cyclohaxane.
SGSL for diethylphthalate used for dimethyl phthalate.
SGSL flr pyrene used for acenaphthylene, benzo(g,h,i)perylene and phenanthrene.
SGSL for chlordane used for alpha- and gamma-chlordane.
SGSL for endrin used for endrin aldehyde.
SGSL for VPH/EPH fractions calculated for online calculator and PPRTVs.
(5) Rationale Codes:
Selection Reason: Above Screening Levels (ASL)
Deletion Reason: No Toxicity Information (NTX)
Essential Nutrient (NUT)
Below Screening Level (BSL)

Definitions:
ug/m3 = micrograms per cubic meter.
COPCs = Chemicals of Potential Concern
ARAR/TBC = Applicable or Relevant and Appropriate Requirement/To Be Considered
RSL = Regional Screening Level
J = Estimated Value
C = Carcinogenic
N = Non-Carcinogenic
N/A = Not Applicable or Not Available
ND = Not Detected

TABLE 3-3.1.RME
EXPOSURE POINT CONCENTRATION SUMMARY
REASONABLE MAXIMUM EXPOSURE
Southwest Properties, Wells G&H Superfund Site Operable Unit 2 Woburn, Massachusetts

	Vanadium	mg/kg	3.35E+01	N/A	3.90E+01 J	3.90E+01	mg/kg	Max	(a)

Notes:
(1) Only COPCs selected on Table 3-2.1 and detected at each exposure point appear.
(2) T - Transformed; N - Normal; NP - Non-parametric; <=6 - sample size too small to calculate 95% UCL
(3) Statistics: Maximum Detected Value (Max); 95% UCL of Transformed Data (95% UCL - T); 95% of Normal Data (95% UCL - N); 95% of Non-parametric Data (95% UCL - NP); Arithmatic Mean (Mean).
(4) Rationale
(a) Due to the small number of detected values, the maximum detected concentration is used.
(b) Shapiro-Wilk W Test indicates data are normally distributed.
(c) Shapiro-Wilk W Test indicates data are log-normally distributed.
(d) Shapiro-Wilk W Test indicates data are neither normally nor log-normally distributed.
(e) Recommended UCL exceeds maximum detected concentration. Therefore, maximum concentration is used for EPC.
(f) Due to high standard deviation, the maximum concentration is used.
(g) When the maximum detected concentration is selected as the RME EPC, the arithmetic mean concentration is selected as the CT EPC.
(h) If the arithmetic mean concentration equals or exceeds the maximum detected concentration, the maximum detected concentration is used as the CT EPC.
J = Estimated concentration
Max = Maximum detected concentration
N/A = Not applicable
UCL = Upper confidence limit
EPC = Exposure point concentration
RME = Reasonable Maximum Exposure
CTE = Central Tendency Exposure

	Vanadium	mg/kg	3.35E+01	N/A	3.90E+01	J	3.35E+01	mg/kg	Mean	(g)

Notes:
(1) Only COPCs selected on Table 3-2.1 and detected at each exposure point appear.
(2) T - Transformed; N - Normal; NP - Non-parametric; <6 - sample size too small to calculate 95% UCL
(3) Statistics: Maximum Detected Value (Max); 95% UCL of Transformed Data (95% UCL - T); 95% of Normal Data (95% UCL - N); 95% of Non-parametric Data (95% UCL - NP); Arithmatic Mean (Mean).
(4) Rationale
(a) Due to the small number of detected values, the maximum detected concentration is used.
(b) Shapiro-Wilk W Test indicates data are normally distributed.
(c) Shapiro-Wilk W Test indicates data are log-normally distributed.
(d) Shapiro-Wilk W Test indicates data are neither normally nor log-normally distributed.
(e) Recommended UCL exceeds maximum detected concentration. Therefore, maximum concentration is used for EPC.
(f) Due to high standard deviation, the maximum concentration is used.
(g) When the maximum detected concentration is selected as the RME EPC, the arithmetic mean concentration is selected as the CT EPC.
(h) If the arithmetic mean concentration equals or exceeds the maximum detected concentration, the maximum detected concentration is used as the CT EPC.

J = Estimated concentration
Max = Maximum detected concentration
N/A = Not applicable
UCL = Upper confidence limit
EPC = Exposure point concentration
RME = Reasonable Maximum Exposure
CTE = Central Tendency Exposure

Notes:
(1) Only COPCs selected on Table 3-2.1 and detected at each exposure point appear.
(2) T - Transformed; N - Normal; NP - Non-parametric; <=6 - sample size too small to calculate 95% UCL
(3) Statistics: Maximum Detected Value (Max); 95% UCL of Transformed Data (95% UCL - T); 95% of Normal Data (95% UCL - N); 95% of Non-parametric Data (95% UCL - NP); Arithmatic Mean (Mean).
(4) Rationale
(a) Due to the small number of detected values, the maximum detected concentration is used.
(b) Shapiro-Wilk W Test indicates data are normally distributed.
(c) Shapiro-Wilk W Test indicates data are log-normally distributed.
(d) Shapiro-Wilk W Test indicates data are neither normally nor log-normally distributed.
(e) Recommended UCL exceeds maximum detected concentration. Therefore, maximum concentration is used for EPC.
(f) Due to high standard deviation, the maximum concentration is used.
(g) When the maximum detected concentration is selected as the RME EPC, the arithmetic mean concentration is selected as the CT EPC.
(h) If the arithmetic mean concentration equals or exceeds the maximum detected concentration, the maximum detected concentration is used as the CT EPC.
J = Estimated concentration
Max = Maximum detected concentration
N/A = Not applicable
UCL = Upper confidence limit
EPC = Exposure point concentration
RME = Reasonable Maximum Exposure
CTE = Central Tendency Exposure

Notes:
(1) Only COPCs selected on Table 3-2.1 and detected at each exposure point appear.
(2) T - Transformed; N - Normal; NP - Non-parametric; <6 - sample size too small to calculate 95% UCL
(3) Statistics: Maximum Detected Value (Max); 95% UCL of Transformed Data (95% UCL - T); 95% of Normal Data (95% UCL - N); 95% of Non-parametric Data (95% UCL - NP); Arithmatic Mean (Mean).
(4) Rationale
(a) Due to the small number of detected values, the maximum detected concentration is used.
(b) Shapiro-Wilk W Test indicates data are normally distributed.
(c) Shapiro-Wilk W Test indicates data are log-normally distributed.
(d) Shapiro-Wilk W Test indicates data are neither normally nor log-normally distributed.
(e) Recommended UCL exceeds maximum detected concentration. Therefore, maximum concentration is used for EPC.
(f) Due to high standard deviation, the maximum concentration is used.
(g) When the maximum detected concentration is selected as the RME EPC, the arithmetic mean concentration is selected as the CT EPC.
(h) If the arithmetic mean concentration equals or exceeds the maximum detected concentration, the maximum detected concentration is used as the CT EPC.
J = Estimated concentration
Max = Maximum detected concentration
N/A = Not applicable
UCL = Upper confidence limit
EPC = Exposure point concentration
RME = Reasonable Maximum Exposure
CTE = Central Tendency Exposure

	Vanadium	mg/kg	2.31E+01	2.86E+01 (N)	6.10E+01	J	2.86E+01	mg/kg	95%UCL-N	(b)

Notes:
(1) Only COPCs selected on Table 3-2.1 and detected at each exposure point appear.
(2) T - Transformed; N - Normal; NP - Non-parametric; <=4 - sample size too small to calculate 95% UCL
(3) Statistics: Maximum Detected Value (Max); 95% UCL of Transformed Data (95% UCL - T); 95% of Normal Data (95% UCL - N); 95% of Non-parametric Data (95% UCL - NP); Arithmatic Mean (Mean).
(4) Rationale
(a) Due to the small number of detected values, the maximum detected concentration is used.
(b) Shapiro-Wilk W Test indicates data are normally distributed.
(c) Shapiro-Wilk W Test indicates data are log-normally distributed.
(d) Shapiro-Wilk W Test indicates data are neither normally nor log-normally distributed.
(e) Recommended UCL exceeds maximum detected concentration. Therefore, maximum concentration is used for EPC.
(f) Due to high standard deviation, the maximum concentration is used.
(g) When the maximum detected concentration is selected as the RME EPC, the arithmetic mean concentration is selected as the CT EPC.
(h) If the arithmetic mean concentration equals or exceeds the maximum detected concentration, the maximum detected concentration is used as the CT EPC.
J = Estimated concentration
Max = Maximum detected concentration
N/A = Not applicable
UCL = Upper confidence limit
EPC = Exposure point concentration
RME = Reasonable Maximum Exposure
CTE = Central Tendency Exposure

Notes:
(1) Only COPCs selected on Table 3-2.1 and detected at each exposure point appear.
(2) T - Transformed; N - Normal; NP - Non-parametric; <4 - sample size too small to calculate 95% UCL
(3) Statistics: Maximum Detected Value (Max); 95% UCL of Transformed Data (95% UCL - T); 95% of Normal Data (95% UCL - N); 95% of Non-parametric Data (95% UCL - NP); Arithmatic Mean (Mean).
(4) Rationale
(a) Due to the small number of detected values, the maximum detected concentration is used.
(b) Shapiro-Wilk W Test indicates data are normally distributed.
(c) Shapiro-Wilk W Test indicates data are log-normally distributed.
(d) Shapiro-Wilk W Test indicates data are neither normally nor log-normally distributed.
(e) Recommended UCL exceeds maximum detected concentration. Therefore, maximum concentration is used for EPC.
(f) Due to high standard deviation, the maximum concentration is used.
(g) When the maximum detected concentration is selected as the RME EPC, the arithmetic mean concentration is selected as the CT EPC.
(h) If the arithmetic mean concentration equals or exceeds the maximum detected concentration, the maximum detected concentration is used as the CT EPC.
J = Estimated concentration
Max = Maximum detected concentration
N/A = Not applicable
UCL = Upper confidence limit
EPC = Exposure point concentration
RME = Reasonable Maximum Exposure
CTE = Central Tendency Exposure

	Aluminum	ug/L	4.58E+02	N/A	4.22E+03	4.22E+03	ug/L	Max	(h)
	Antimony	ug/L	1.60E+00	N/A	4.60E+00	4.60E+00	ug/L	Max	(h)
	Arsenic	ug/L	1.54E+01	N/A	3.89E+02	3.89E+02	ug/L	Max	(h)
	Cadmium	ug/L	4.26E-01	N/A	8.20E-01 J	8.20E-01	ug/L	Max	(h)
	Cobalt	ug/L	6.57E+00	N/A	1.60E+01 J	1.60E+01	ug/L	Max	(h)
	Iron	ug/L	4.26E+03	N/A	3.38E+04	3.38E+04	ug/L	Max	(h)
	Lead	ug/L	5.26E+00	N/A	1.29E+02	N/A	ug/L		
	Manganese	ug/L	6.15E+02	N/A	4.89E+03	4.89E+03	ug/L	Max	(h)
	Selenium	ug/L	2.73E+00	N/A	1.14E+01 J	1.14E+01	ug/L	Max	(h)
	Vanadium	ug/L	3.91E+00	N/A	1.07E+01	1.07E+01	ug/L	Max	(h)

(1) Only COPCs selected on Table 3-2.2 appear.

(2) T - Transformed; N - Normal; NP - Non-parametric; <4 - sample size too small to calculate 95% UCL

(3) Statistics: Maximum Detected Value (Max); 95% UCL of Transformed Data (95% UCL - T); 95% of Normal Data (95% UCL - N); 95% of Non-parametric Data (95% UCL - NP); Arithmatic Mean (Mean).

(4) Rationale

(a) Due to small sample size (<4), the maximum detected concentration is used.
(b) Shapiro-Wilk W Test indicates data are normally distributed.
(c) Shapiro-Wilk W Test indicates data are log-normally distributed.
(d) Shapiro-Wilk W Test indicates data are neither normally nor log-normally distributed.
(e) Recommended UCL exceeds maximum detected concentration. Therefore, maximum concentration is used for EPC.
(f) When the maximum detected concentration is selected as the RME EPC, the arithmetic mean concentration is selected as the CT EPC.
(g) If the arithmetic mean concentration equals or exceeds the maximum detected concentration, the maximum detected concentration is used as the CT EPC.
(h) Maximum concentration used for EPC exposures.
(i) Mean concentration used for EPC exposures.

J = Estimated concentration
Max = Maximum detected concentration
N/A = Not applicable
UCL = Upper confidence limit
EPC = Exposure point concentration
RME = Reasonable Maximum Exposure
CTE = Central Tendency Exposure

	Vanadium	ug/L	3.91E+00	N/A	1.07E+01	3.91E+00	ug/L	Mean	(i)

(1) Only COPCs selected on Table 3-2.2 appear.

(2) T - Transformed; N - Normal; NP - Non-parametric; <4 - sample size too small to calculate 95% UCL

(3) Statistics: Maximum Detected Value (Max); 95% UCL of Transformed Data (95% UCL - T); 95% of Normal Data (95% UCL - N); 95% of Non-parametric Data (95% UCL - NP); Arithmatic Mean (Mean).

(4) Rationale

(a) Due to small sample size (<4), the maximum detected concentration is used.

(b) Shapiro-Wilk W Test indicates data are normally distributed.

(c) Shapiro-Wilk W Test indicates data are log-normally distributed.

(d) Shapiro-Wilk W Test indicates data are neither normally nor log-normally distributed

(e) Recommended UCL exceeds maximum detected concentration. Therefore, maximum concentration is used for EPC

(f) When the maximum detected concentration is selected as the RME EPC, the arithmetic mean concentration is selected as the CT EPC

(g) If the arithmetic mean concentration equals or exceeds the maximum detected concentration, the maximum detected concentration is used as the CTE EPC

(h) Maximum concentration used for EPC exposures.

(i) Mean concentration used for EPC exposures.

J = Estimated concentration

Max = Maximum detected concentration

N/A = Not applicable

UCL = Upper confidence limit

EPC = Exposure point concentration

RME = Reasonable Maximum Exposure

CTE = Central Tendency Exposure

TABLE 3-3.5.RME

EXPOSURE POINT CONCENTRATION SUMMARY

REASONABLE MAXIMUM EXPOSURE

Southwest Properties, Wells G & H Superfund Site Operable Unit 2, Woburn, Massachusetts

Scenario Timeframe:	Future
Medium:	Groundwater
Exposure Medium:	Shallow Groundwater

Exposure Point (1)	CAS Number	Chemical of Potential Concern	Units	Arithmetic Mean	95% UCL (Distribution) (2)	Maximum Concentration (Qualifier)	Exposure Point Concentration			
							Value	Units	Statistic (3)	Rationale (4)

(1) Only COPCs selected on Table 3-2.2 and detected at each exposure point appear.

(2) T - Transformed; N - Normal; NP - Non-parametric; <9 - sample size too small to calculate 95% UCL

(3) Statistics: Maximum Detected Value (Max); 95% UCL of Transformed Data (95% UCL - T); 95% of Normal Data (95% UCL - N); 95% of Non-parametric Data (95% UCL - NP); Arithmatic Mean (Mean).

(4) Rationale

(a) Due to small size of distinct detected values, the maximum detected concentration is used.
(b) Shapiro-Wilk W Test indicates data are normally distributed.
(c) Shapiro-Wilk W Test indicates data are log-normally distributed.
(d) Shapiro-Wilk W Test indicates data are neither normally nor log-normally distributed.
(e) Recommended UCL exceeds maximum detected concentration. Therefore, maximum concentration is used for EPC.
(f) Due to high standard deviation, the maximum concentration is used.
(g) When the maximum detected concentration is selected as the RME EPC, the arithmetic mean concentration is selected as the CT EPC.
(h) If the arithmetic mean concentration equals or exceeds the maximum detected concentration, the maximum detected concentration is used as the CT EPC.

J = Estimated concentration
Max = Maximum detected concentration
N/A = Not applicable
UCL = Upper confidence limit
EPC = Exposure point concentration
RME = Reasonable Maximum Exposure
CTE = Central Tendency Exposure

TABLE 3-3.5.CTE

EXPOSURE POINT CONCENTRATION SUMMARY

CENTRAL TENDENCY EXPOSURE

Southwest Properties, Wells G & H Superfund Site Operable Unit 2, Woburn, Massachusetts

Scenario Timeframe:	Future
Medium:	Groundwater
Exposure Medium:	Shallow Groundwater

Exposure Point (1)	CAS Number	Chemical of Potential Concern	Units	Arithmetic Mean	95% UCL (Distribution) (2)	Maximum Concentration (Qualifier)	Exposure Point Concentration			
							Value	Units	Statistic (3)	Rationale (4)

(1) Only COPCs selected on Table 3-2.2 and detected at each exposure point appear.
(2) T - Transformed; N - Normal; NP - Non-parametric; <9 - sample size too small to calculate 95% UCL

(3) Statistics: Maximum Detected Value (Max); 95% UCL of Transformed Data (95% UCL - T); 95% of Normal Data (95% UCL - N); 95% of Non-parametric Data (95% UCL - NP); Arithmatic Mean (Mean).
(4) Rationale
(a) Due to small size of distinct detected values, the maximum detected concentration is used.
(b) Shapiro-Wilk W Test indicates data are normally distributed.
(c) Shapiro-Wilk W Test indicates data are log-normally distributed.
(d) Shapiro-Wilk W Test indicates data are neither normally nor log-normally distributed.
(e) Recommended UCL exceeds maximum detected concentration. Therefore, maximum concentration is used for EPC.
(f) Due to high standard deviation, the maximum concentration is used.
(g) When the maximum detected concentration is selected as the RME EPC, the arithmetic mean concentration is selected as the CT EPC.
(h) If the arithmetic mean concentration equals or exceeds the maximum detected concentration, the maximum detected concentration is used as the CT EPC.

J = Estimated concentration
Max = Maximum detected concentration
N/A = Not applicable
UCL = Upper confidence limit
EPC = Exposure point concentration
RME = Reasonable Maximum Exposure
CTE = Central Tendency Exposure

(1) Only COPCs selected on Table 3-2.3 appear.
(2) T - Transformed; N - Normal; NP - Non-parametric; <=9 - sample size too small to calculate 95% UCL
(3) Statistics: Maximum Detected Value (Max); 95% UCL of Transformed Data (95% UCL - T); 95% of Normal Data (95% UCL - N); 95% of Non-parametric Data (95% UCL - NP); Arithmatic Mean (Mean).
(4) Rationale
(a) Due to small sample size (<=9), the maximum detected concentration is used.
(b) Shapiro-Wilk W Test indicates data are normally distributed.
(c) Shapiro-Wilk W Test indicates data are log-normally distributed.
(d) Shapiro-Wilk W Test indicates data are neither normally nor log-normally distributed.
(e) Recommended UCL exceeds maximum detected concentration. Therefore, maximum concentration is used for EPC.
(f) Due to high standard deviation, the maximum concentration is used.
(g) When the maximum detected concentration is selected as the RME EPC, the arithmetic mean concentration is selected as the CT EPC.
(h) If the arithmetic mean concentration equals or exceeds the maximum detected concentration, the maximum detected concentration is used as the CT EPC.
J = Estimated concentration
Max = Maximum detected concentration
N/A = Not applicable
UCL = Upper confidence limit
EPC = Exposure point concentration
RME = Reasonable Maximum Exposure
CTE = Central Tendency Exposure

Adult SA term assumes exposure to face, forearms, hands, and lower legs.

Young child SA term assumes exposure to face, forearms, hands, lower legs, and feet.

Older child SA term assumes exposure to hands, lower legs, and feet.

Adult AF term is geometric mean value for adult gardeners.

Older child and young child AF term is geometric mean value for children playing in wet soil.

EF for direct contact for the older child trespasser assumes 2 days per week, May through October.

EF for direct contact for the adult and young child recreational user assumes 3 days per week, May through October.

Selenium	Subchronic	5.00E-03	mg/kg-day	(4)	5.00E-03	mg/kg-day	Liver/Skin	3	IRIS	03/01/14
Thallium	Chronic	1.00E-05	mg/kg-day	(4)	1.00E-05	mg/kg-day	Skin	3000	PPRTV	10/08/10
Thallium	Subchronic	4.00E-05	mg/kg-day	(4)	4.00E-05	mg/kg-day	Skin	1000	PPRTV	10/08/10
Vanadium	Chronic	5.00E-03	mg/kg-day	(4)	5.00E-03	mg/kg-day	Skin	100	IRIS	03/01/14
Vanadium	Subchronic	5.00E-03	mg/kg-day	(4)	5.00E-03	mg/kg-day	Skin	100	IRIS	03/01/14

(1) Oral Absorption Efficiencies from Exhibit 4-1, RAGS Part E, USEPA 2001.

(2) Calculated as: (oral RfD) x (oral to dermal adjustment factor).

(3) RfD for Aroclor 1254 used as a surrogate for Total PCBs (High risk and persistence; upper-bound slope factor).
RfDs for managanese are based on total allowable intake (10 mg/day) minus the background intake (5 mg/day). The remaining intake (5 mg/day) is divided by 70 kg.
RfD for thallium is based on thallium sulfate.
RfD for chlordane used as a surrogate for alpha-and gamma-chlordane.
RfD for mercury (inorganic) based on mercuric chloride; for mercury (organic), based on methylmercury.
RfD for nickel is based on nickel, soluble salts.
RfD for vanadium is based on vanadium pentoxide.

(4) Oral absorption efficiency exceeds 50%. Therefore, no adjustment of the oral reference dose is necessary (USEPA, 2001).

(5) Used for all media and exposures except oral exposures to sediment (see Table 3-5.3).

(6) See Appendix B.6 for lead model calculations.

When the chronic RfD is based on a subchronic study, a subchronic RfD has been developed by the elimination of the 10-fold uncertainty factor for subchronic to chronic adjustment. If no subchronic data are available, the chronic RfD has been adopted as the subchronic RfD.

IRIS = Integrated Risk Information System

HEAST = Health Effects Assessment Summary Tables

N/A = Not Applicable/Not Available

PPRTV = Provisional Peer-Reviewed Toxicity Value

CalEPA = California Environmental Protection Agency

IRIS = Integrated Risk Information System

PPRTV = Provisional Peer-Reviewed Toxicity Value

CalEPA = California Environmental Protection Agency

HEAST = Health Effects Assessment Summary Tables

RME = Reasonable Maximum Exposure

CT = Central Tendency

N/A = Not Applicable

(1) RfC for naphthalene used as a surrogate for 2-methylnaphthalene.
RfC for mercury (inorganic) based on elemental mercury; for mercury (organic), based on methylmercury.
RfC for nickel is based on nickel, soluble salts.

(2) See Appendix B.6 for lead model calculations.

TABLE 3-5.3

NON-CANCER TOXICITY DATA -- SPECIAL CASE CHEMICALS

Southwest Properties, Wells G&H Superfund Site Operable Unit 2 Woburn, Massachusetts

Chemical of Potential Concern	Chronic/ Subchronic	Parameter			Primary Target Organ(s)	Combined Uncertainty/Modifying Factors	Parameter:Target Organ(s)	
		Name	Value	Units			Source(s)	Date(s)
Arsenic	Chronic	Sediment Oral RfD adjusted for site-specific relative bioavailability	5.9E-04	mg/kg-day	skin	3	IRIS	02/01/03

RfD (adjusted) = RfD (IRIS) / RBA

IRIS = Integrated Risk Information System

RBA = Relative Bioavailability = 0.51 (site-specific)

CalEPA = California Environmental Protection Agency

HEAST = Health Effects Assessment Summary Tables

NJDEP = New Jersey Department of Environmental Protection

Slope factor for chlordane used as a surrogate for alpha- and gamma chlordane.

Slope factor for benzo(a)pyrene, along with the appropriate relative potency factor (USEPA, 1993), used for the other carcinogenic PAHs.

Weight of evidence for mercury (inorganic) based on elemental mercury; for mercury (organic), based on methylmercury.

For PCBs, the RME slope factor is presented. A slope factor of 1 (mg/kg-day)-1 is used for CT risk estimates (USEPA, 2012).

EPA Group:

A - Human carcinogen

B1 - Probable human carcinogen - indicates that limited human d

B2 - Probable human carcinogen - indicates sufficient evidence ir inadequate or no evidence in humans

C - Possible human carcinogen

D - Not classifiable as a human carcinogen (by the oral route)

E - Evidence of noncarcinogenicity

(1) Oral absorption efficiency exceeds 50%. Therefore, no adjustment of the oral slope factor is necessary.

(2) Calculated as: (oral slope factor) / (oral to dermal adjustment factor)

(3) Used for all media and exposures except oral exposures to sediment (see Table 3-6.3).

(4) See Appendix B.6 for lead model calculations.

(5) Value based on the toxicity of 2,3,7,8-TCDD

(6) For the early life cancer risk calculation for trichloroethene, slope factors of 9.3E-03 (mg/kg-day)-1 for the kidney tumor endpoint and 3.7E-02 (mg/kg-day)-1 for the non-hodgkins lymphoma/liver tumor endpoint are used.

Notes

Early-life cancer risk calculations for carcinogenic PAHs, methylene chloride and chromium VI calculated by multiplying the result by the default age-dependent adjustment factor (ADAF) of 3 for 4/6 of the result (ages 12-16) and an ADAF of 1 for 2/6 of the result (ages 17-18).

Early-life cancer risk calculations for trichloroethene calculated by multiplying the intake by the slope factor or unit risk for the kidney tumor endpoint and the default age-dependent adjustment factor (ADAF) of 3 for 4/6 of the result (ages 12-16) and an ADAF of 1 for 2/6 of the result (ages 17-18).

No early-life adjustment is made for the non-hodgkins lymphoma/liver tumor endpoint.

Notes

Early-life cancer risk calculations for carcinogenic PAHs, methylene chloride and chromium VI calculated by multiplying the result by the default age-dependent adjustment factor (ADAF) of 3 for 4/6 of the result (ages 12-16) and an ADAF of 1 for 2/6 of the result (ages 17-18).

Early-life cancer risk calculations for trichloroethene calculated by multiplying the intake by the slope factor or unit risk for the kidney tumor endpoint and the default age-dependent adjustment factor (ADAF) of 3 for 4/6 of the result (ages 12-16) and an ADAF of 1 for 2/6 of the result (ages 17-18).

No early-life adjustment is made for the non-hodgkins lymphoma/liver tumor endpoint.

Notes

Early-life cancer risk calculations for carcinogenic PAHs, methylene chloride and chromium VI calculated by multiplying the result by the default age-dependent adjustment factor (ADAF) of 3 for 4/6 of the result (ages 12-16) and an ADAF of 1 for 2/6 of the result (ages 17-18).

Early-life cancer risk calculations for trichloroethene calculated by multiplying the intake by the slope factor or unit risk for the kidney tumor endpoint and the default age-dependent adjustment factor (ADAF) of 3 for 4/6 of the result (ages 12-16) and an ADAF of 1 for 2/6 of the result (ages 17-18).

No early-life adjustment is made for the non-hodgkins lymphoma/liver tumor endpoint.

Notes

Early-life cancer risk calculations for carcinogenic PAHs, methylene chloride and chromium VI calculated by multiplying the result by the default age-dependent adjustment factor (ADAF) of 3 for 4/6 of the result (ages 12-16) and an ADAF of 1 for 2/6 of the result (ages 17-18).

Early-life cancer risk calculations for trichloroethene calculated by multiplying the intake by the slope factor or unit risk for the kidney tumor endpoint and the default age-dependent adjustment factor (ADAF) of 3 for 4/6 of the result (ages 12-16) and an ADAF of 1 for 2/6 of the result (ages 17-18).

No early-life adjustment is made for the non-hodgkins lymphoma/liver tumor endpoint.

Notes

Early-life cancer risk calculations for carcinogenic PAHs, methylene chloride and chromium VI calculated by multiplying the result by the default age-dependent adjustment factor (ADAF) of 3 for 10/24 of the result (ages 7-16) and an ADAF of 1 for 14/24 of the result (ages 17-30).

Early-life cancer risk calculations for trichloroethene calculated by multiplying the intake by the slope factor or unit risk for the kidney tumor endpoint and the default age-dependent adjustment factor (ADAF) of 3 for 10/24 of the result (ages 7-16) and an ADAF of 1 for 14/24 of the result (ages 17-30).

No early-life adjustment is made for the non-hodgkins lymphoma/liver tumor endpoint.

Notes

Early-life cancer risk calculations for carcinogenic PAHs, methylene chloride and chromium VI calculated by multiplying the result by the default age-dependent adjustment factor (ADAF) of 3 for 10/24 of the result (ages 7-16) and an ADAF of 1 for 14/24 of the result (ages 17-30).

Early-life cancer risk calculations for trichloroethene calculated by multiplying the intake by the slope factor or unit risk for the kidney tumor endpoint and the default age-dependent adjustment factor (ADAF) of 3 for 10/24 of the result (ages 7-16) and an ADAF of 1 for 14/24 of the result (ages 17-30).

No early-life adjustment is made for the non-hodgkins lymphoma/liver tumor endpoint.

Notes

Early-life cancer risk calculations for carcinogenic PAHs, methylene chloride and chromium VI calculated by multiplying the result by the default age-dependent adjustment factor (ADAF) of 10 for 2/6 of the result (ages 1-2) and an ADAF of 3 for 4/6 of the result (ages 3-6).

Early-life cancer risk calculations for vinyl chloride added to standard cancer risk calculations [chronic daily intake (CDI) x CSF or Unit Risk]. Exposure parameters noted below are defined in Table 3-4.5.RME for the young child (ages 1-6).

Inhalation early-life cancer risk = EPC (ug/L) x Unit Risk (ug/m3)-1 x K (L/m3)

Ingestion early-life cancer risk = EPC (ug/L) x CSF (mg/kg-day)-1 x IR (L/day) x CF (0.001 mg/ug) / BW (kg)

Dermal early-life cancer risk = SA (cm2) x DAevent (mg/cm2-event) x CSF (mg/kg-day)-1 x EV (event/day) / BW (kg)

Early-life cancer risk calculations for trichloroethene calculated by multiplying the intake by the slope factor or unit risk for the kidney tumor endpoint and the default age-dependent adjustment factor (ADAF) of 10 for 2/6 of the result (ages 1-2) and an ADAF of 3 for 4/6 of the result (ages 3-6).

No early-life adjustment is made for the non-hodgkins lymphoma/liver tumor endpoint.

Notes

Early-life cancer risk calculations for carcinogenic PAHs, methylene chloride and chromium VI calculated by multiplying the result by the default age-dependent adjustment factor (ADAF) of 10 for 2/6 of the result (ages 1-2) and an ADAF of 3 for 4/6 of the result (ages 3-6).

Early-life cancer risk calculations for vinyl chloride added to standard cancer risk calculations [chronic daily intake (CDI) x CSF or Unit Risk]. Exposure parameters noted below are defined in Table 3-4.5.CTE for the young child (ages 1-6).

Inhalation early-life cancer risk = EPC (ug/L) x Unit Risk (ug/m3)-1 x K (L/m3)

Ingestion early-life cancer risk = EPC (ug/L) x CSF (mg/kg-day)-1 x IR (L/day) x CF (0.001 mg/ug) / BW (kg)

Dermal early-life cancer risk = SA (cm2) x DAevent (mg/cm2-event) x CSF (mg/kg-day)-1 x EV (event/day) / BW (kg)

Early-life cancer risk calculations for trichloroethene calculated by multiplying the intake by the slope factor or unit risk for the kidney tumor endpoint and the default age-dependent adjustment factor (ADAF) of 10 for 2/6 of the result (ages 1-2) and an ADAF of 3 for 4/6 of the result (ages 3-6).

No early-life adjustment is made for the non-hodgkins lymphoma/liver tumor endpoint.

											N/A					N/A

Notes

Early-life cancer risk calculations for carcinogenic PAHs, methylene chloride and chromium VI calculated by multiplying the result by the default age-dependent adjustment factor (ADAF) of 3 for 10/24 of the result (ages 7-16) and an ADAF of 1 for 14/24 of the result (ages 17-30).

Early-life cancer risk calculations for trichloroethene calculated by multiplying the intake by the slope factor or unit risk for the kidney tumor endpoint and the default age-dependent adjustment factor (ADAF) of 3 for 10/24 of the result (ages 7-16) and an ADAF of 1 for 14/24 of the result (ages 17-30).

No early-life adjustment is made for the non-hodgkins lymphoma/liver tumor endpoint.

Notes

Early-life cancer risk calculations for carcinogenic PAHs, methylene chloride and chromium VI calculated by multiplying the result by the default age-dependent adjustment factor (ADAF) of 3 for 10/24 of the result (ages 7-16) and an ADAF of 1 for 14/24 of the result (ages 17-30).

Early-life cancer risk calculations for trichloroethene calculated by multiplying the intake by the slope factor or unit risk for the kidney tumor endpoint and the default age-dependent adjustment factor (ADAF) of 3 for 10/24 of the result (ages 7-16) and an ADAF of 1 for 14/24 of the result (ages 17-30).

No early-life adjustment is made for the non-hodgkins lymphoma/liver tumor endpoint.

Notes

Early-life cancer risk calculations for carcinogenic PAHs, methylene chloride and chromium VI calculated by multiplying the result by the default age-dependent adjustment factor (ADAF) of 10 for 2/6 of the result (ages 1-2) and an ADAF of 3 for 4/6 of the result (ages 3-6).

Early-life cancer risk calculations for vinyl chloride added to standard cancer risk calculations [chronic daily intake (CDI) x CSF]. Exposure parameters noted below are defined in Table 3-4.5.RME for the young child (ages 1-6).

Ingestion early-life cancer risk = EPC (mg/kg) x CSF (mg/kg-day)-1 x IR (mg/day) x CF (0.000001 kg/mg) / BW (kg)

Dermal early-life cancer risk = EPC (mg/kg) x SA (cm2) x AF (mg/cm2) x CSF (mg/kg-day)-1 x ABS (event/day) x CF (0.000001 kg/mg)/ BW (kg)

Early-life cancer risk calculations for trichloroethene calculated by multiplying the intake by the slope factor or unit risk for the kidney tumor endpoint and the default age-dependent adjustment factor (ADAF) of 10 for 2/6 of the result (ages 1-2) and an ADAF of 3 for 4/6 of the result (ages 3-6).

No early-life adjustment is made for the non-hodgkins lymphoma/liver tumor endpoint.

Notes

Early-life cancer risk calculations for carcinogenic PAHs, methylene chloride and chromium VI calculated by multiplying the result by the default age-dependent adjustment factor (ADAF) of 10 for 2/6 of the result (ages 1-2) and an ADAF of 3 for 4/6 of the result (ages 3-6).

Early-life cancer risk calculations for vinyl chloride added to standard cancer risk calculations [chronic daily intake (CDI) x CSF]. Exposure parameters noted below are defined in Table 3-4.5.RME for the young child (ages 1-6).

Ingestion early-life cancer risk = EPC (mg/kg) x CSF (mg/kg-day)-1 x IR (mg/day) x CF (0.000001 kg/mg) / BW (kg)

Dermal early-life cancer risk = EPC (mg/kg) x SA (cm2) x AF (mg/cm2) x CSF (mg/kg-day)-1 x ABS (event/day) x CF (0.000001 kg/mg)/ BW (kg)

Early-life cancer risk calculations for trichloroethene calculated by multiplying the intake by the slope factor or unit risk for the kidney tumor endpoint and the default age-dependent adjustment factor (ADAF) of 10 for 2/6 of the result (ages 1-2) and an ADAF of 3 for 4/6 of the result (ages 3-6).

No early-life adjustment is made for the non-hodgkins lymphoma/liver tumor endpoint.
