

US EPA ARCHIVE DOCUMENT

Final
Total Maximum Daily Loads
for
Dissolved Oxygen and Nutrients
in
Crabgrass Creek - WBID 3073
and
Jane Green Creek – WBID 3084

May 2013

Region4 serving the
southeast

In compliance with the provisions of the Federal Clean Water Act, 33 U.S.C §1251 et. seq., as amended by the Water Quality Act of 1987, P.L. 400-4, the U.S. Environmental Protection Agency is hereby establishing the Total Maximum Daily Load (TMDL) for Dissolved Oxygen and Nutrients in the Upper St. Johns River Basin (WBIDs 3073, 3084). Subsequent actions must be consistent with this TMDL.

SUMMARY SHEET

Total Maximum Daily Load (TMDL)

1998 303(d) Listed Waterbodies for TMDLs addressed in this report:

WBID	Segment Name	Class and Waterbody Type	Major River Basin	HUC	County	State
3073	Crabgrass Creek	Class III Freshwater	Upper St. Johns	03080101	Osceola	Florida
3084	Jane Green Creek	Class III Freshwater	Upper St. Johns	03080101	Osceola	Florida

TMDL Endpoints/Targets:

Nutrients and Dissolved Oxygen

TMDL Technical Approach:

The TMDL allocations were determined by analyzing the effects of BOD, TN, and TP loads on DO concentrations in the waterbody. A watershed model was used to predict delivery of pollutant loads to the waterbody, and a WASP Eutrophication model was used to evaluate the in-stream impacts of the pollutant loads.

TMDL Waste Load and Load Allocation for WBIDs 3073 and 3084

Constituent	Current Condition		TMDL Condition		MS4	LA
	WLA (kg/yr)	LA (kg/yr)	WLA (kg/yr)	LA (kg/yr)	% Reduction	% Reduction
BOD	NA	919,833	NA	716,943	NA	22%
Total Nitrogen	NA	379,496	NA	342,682	NA	10%
Total Phosphorus	NA	61,073	NA	39,855	NA	35%

Endangered Species Present (Yes or Blank):

TMDL Considers Point Source, Non-point Source, or Both: Non-point Source

Major NPDES Discharges to surface waters addressed in USEPA TMDL: None

1. Introduction

Section 303(d) of the Clean Water Act requires each state to list those waters within its boundaries for which technology based effluent limitations are not stringent enough to protect any water quality standard applicable to such waters. Listed waters are prioritized with respect to designated use classifications and the severity of pollution. In accordance with this prioritization, states are required to develop Total Maximum Daily Loads (TMDLs) for those water bodies that are not meeting water quality standards. The TMDL process establishes the allowable loadings of pollutants or other quantifiable parameters for a waterbody based on the relationship between pollution sources and in-stream water quality conditions, so that states can establish water quality based controls to reduce pollution from both point and nonpoint sources and restore and maintain the quality of their water resources (USEPA, 1991).

The Florida Department of Environmental Protection (FDEP) developed a statewide, watershed-based approach to water resource management. Under the watershed management approach, water resources are managed on the basis of natural boundaries, such as river basins, rather than political boundaries. The watershed management approach is the framework FDEP uses for implementing TMDLs. The state's 52 basins are divided into five groups and water quality is assessed in each group on a rotating five-year cycle. FDEP also established five water management districts (WMD) responsible for managing ground and surface water supplies in the counties encompassing the districts. Crabgrass Creek and Jane Green Creek are both located in the Upper St. Johns River Basin and are Group 3 waterbodies managed by the St. Johns River Water Management District (SJRWMD).

For the purpose of planning and management, the WMD divided the districts into planning units defined as either an individual primary tributary basin or a group of adjacent primary tributary basins with similar characteristics. Crabgrass Creek and Jane Green Creek are located within the Jane Green Creek Planning Unit. These planning units contain smaller, hydrological based units called drainage basins, which are further divided by FDEP into "water segments". A water segment usually contains only one unique waterbody type (stream, lake, canal, etc.) and is about 5 square miles. Unique numbers or waterbody identification (WBIDs) numbers are assigned to each water segment. This TMDL report addresses WBIDs 3073 and 3084 (Crabgrass Creek and Jane Green Creek, respectively).

2. Problem Definition

To determine the status of surface water quality in Florida, three categories of data – chemistry data, biological data, and fish consumption advisories – were evaluated to determine potential impairments. The level of impairment is defined in the Identification of Impaired Surface Waters Rule (IWR), Section 62-303 of the Florida Administrative Code (FAC). The IWR is FDEP's methodology for determining whether waters should be included on the state's planning list and verified list. Potential impairments are determined by assessing whether a waterbody meets the criteria for inclusion on the planning list. Once a waterbody is on the planning list, additional data and information will be collected and examined to determine if the water should be included on the verified list.

The TMDLs addressed in this document are being established pursuant to commitments made by the United States Environmental Protection Agency (USEPA) in the 1998 Consent Decree in the Florida TMDL lawsuit (Florida Wildlife Federation, et al. v. Carol Browner, et al., Civil Action No. 4: 98CV356-WS, 1998). The Consent Decree established a schedule for TMDL development for waters listed on Florida's USEPA approved 1998 section 303(d) list. The 1998 section 303(d) list identified numerous WBIDs in the Upper St. Johns River Basin as not meeting Water Quality Standards (WQS). After assessing all readily available water quality data, USEPA is responsible for developing TMDLs for WBIDs 3073 (Crabgrass Creek) and 3084 (Jane Green Creek). The geographic location of these WBID is shown in Figure 1. The parameters addressed in these TMDLs are Dissolved Oxygen and Nutrients.

Figure 1. Location Map Crabgrass Creek (WBID 3073) and Jane Green Creek (WBID 3084)

3. Watershed Description

The Jane Green Creek Planning Unit covers over 260 square miles and is located in the southeastern portion of Osceola County. The planning unit is delineated into 24 WBIDs which are all designated as Class III waters. Crabgrass Creek empties into Jane Green Creek, which enters the St. Johns River between Lakes Hell'n Blazes and Sawgrass. Figure 2 depicts

the delineated watershed used for analysis in this TMDL report and the location of WBIDs 3073 and 3084 within that watershed.

Figure 2. Crabgrass and Jane Green Watershed

In order to identify possible pollutant sources in the watershed, the latest landuse coverage was obtained from the FDEP. The landuses are based on 2004 land cover features and are classified using the Level 1 Florida Landuse Classification Code (FLUCC). As can be seen in Figure 3, landuse in the Crabgrass Creek and Jane Green Creek watershed is largely agriculture. Over 55 percent of Crabgrass and Jane Green Watershed consists of agriculture. The second largest landuse classification in the watershed is wetlands, consisting of 25 percent, while urban landuse only consists of less than one percent. See Figures 4, 5 and 6 for the complete breakdown of landuse within the watershed and each WBID.

Figure 3. Landuse in the Crabgrass Creek and Jane Green Creek Watershed

Figure 4. Landuse Distribution in Watershed

Figure 5. Landuse Distribution in Crabgrass Creek (WBID 3073)

Figure 6. Landuse Distribution in Jane Green Creek (WBID 3084)

4. Water Quality Standards/TMDL Targets

The TMDL reduction scenarios were done to achieve Florida's dissolved oxygen concentration of 5 mg/L and ensure balanced flora and fauna within these WBIDs or establish the TMDL to be consistent with a natural condition if the dissolved oxygen standard cannot be achieved.

4.1 Designated Uses

Florida has classified its waters based on the designated uses those waters are expected to support. Waters classified as Class I waters are designated for Potable Water Supply; Class II waters are designated for Shellfish Propagation or Harvesting, and Class III waters are designated for Recreation, Propagation and Maintenance of a Healthy, Well-Balanced Population of Fish and Wildlife. Designated use classifications are described in Florida's water quality standards at section 62-302.400, F.A.C.

The waterbodies addressed in this report are Class III waters. WBIDs 3073 and 3084 are Class III Freshwater.

4.2 Water quality criteria

Water quality criteria for protection of all classes of waters are established in Section 62-302.530, F.A.C. Individual criteria should be considered in conjunction with other provisions in water quality standards, including Section 62-302.500 F.A.C., which established minimum criteria that apply to all waters unless alternative criteria are specified. Section 62-302.530, F.A.C. Several of the WBIDs addressed in this report were listed due to elevated concentrations of chlorophyll *a*. While FDEP does not have a streams water quality standard specifically for chlorophyll *a*, elevated levels of chlorophyll *a* are frequently associated with nonattainment of the narrative nutrient standard, which is described below.

4.3 Nutrient Criteria

In 1979, FDEP adopted a narrative criterion for nutrients. FDEP recently adopted numeric nutrient criteria for many Class III waters in the state, including streams, lakes, springs, and estuaries, which numerically interprets part of the state narrative criterion for nutrients. On November 30, 2012, EPA approved those criteria as consistent with the requirements of the CWA. Estuary specific criteria for a number of estuaries, as set out in 62-302.532(1), are effective for state law purposes. The remainder of the state criteria, however, are not yet effective for state law purposes.

In December 2010, EPA promulgated numeric nutrient criteria for Class I/III inland waters in Florida, including lakes and streams. On February 18, 2012, the federally promulgated criteria for lakes and springs were upheld by the U.S. District Court for the Northern District of Florida. Those criteria became effective on January 7, 2013. The Court invalidated the

streams criteria and remanded those criteria back to EPA. EPA repropose the streams criteria on November 30, 2012.

Therefore, for lakes and springs in Florida, the applicable nutrient water quality criteria for CWA purposes are the federally promulgated criteria. For those estuaries identified in 62-302.532(1), the applicable nutrient water quality criteria for CWA purposes are FDEP's estuary criteria. For streams and the remaining estuaries in Florida, the applicable nutrient water quality standard for CWA purposes remains Florida's narrative nutrient criterion.

4.3.1 Narrative Nutrient Criteria

Florida's narrative nutrient criteria for Class I, II, and III waters provide:

The discharge of nutrients shall continue to be limited as needed to prevent violations of other standards contained in this chapter. Man induced nutrient enrichment (total nitrogen and total phosphorus) shall be considered degradation in relation to the provisions of Sections 62-302.300, 62-302.700, and 62-4.242. Section 62-302.530(47)(a), F.A.C.

In no case shall nutrient concentrations of a body of water be altered so as to cause an imbalance in natural populations of aquatic flora or fauna. Section 62-302.530(47)(b), F.A.C.

Chlorophyll and DO levels are often used to indicate whether nutrients are present in excessive amounts. The target for this TMDL is based on levels of nutrients necessary to prevent violations of Florida's DO criterion, set out below.

4.3.2 Inland Nutrient Criteria for streams

Florida's recently adopted numeric nutrient criteria interprets the narrative water quality criterion for nutrients in paragraph 62-302.530(48)(b), F.A.C. See section 62-302.531(2). While not yet effective as water quality criteria, the FDEP's numeric nutrient criteria represent the state's most recent interpretation of the second part of Florida's narrative criteria, set out at paragraph 62-302.530(47)(b), F.A.C. See section 62-302.531(2). Unless otherwise stated, where the EPA refers to the state nutrient rule in this TMDL, that rule is referenced as the state's interpretation of the narrative criterion. In addition, the first part of the narrative criteria, at paragraph 62-302.530(47)(a), F.A.C., also remains applicable to all Class I, II and III waters in Florida.

Florida's rule applies to streams. For streams that do not have a site specific criteria, Florida's rule provides for biological information to be considered together with nutrient thresholds to determine whether a waterbody is attaining 62-302.531(2)(c), F.A.C. The rule provides that the nutrient criteria are attained in a stream segment where information on chlorophyll a levels, algal mats or blooms, nuisance macrophyte growth, and changes in algal species composition indicates there are no imbalances in flora and either the average score of at least two temporally independent SCIs

performed at representative locations and times is 40 or higher, with neither of the two most recent SCI scores less than 35, or the nutrient thresholds set forth in Table 1 below are achieved. See section 62-302.531(2)(c).

Florida's rule provides that numeric nutrient criteria are expressed as a geometric mean, and concentrations are not to be exceeded more than once in any three calendar year period. Section 62-302.200 (25)(e), F.A.C.

Table 1 Inland numeric nutrient criteria

Nutrient Watershed Region	Total Phosphorus Nutrient Threshold	Total Nitrogen Nutrient Threshold
Panhandle West	0.06 mg/L	0.67 mg/L
Panhandle East	0.18 mg/L	1.03 mg/L
North Central	0.30 mg/L	1.87 mg/L
Peninsular	0.12 mg/L	1.54 mg/L
West Central	0.49 mg/L	1.65 mg/L
South Florida	No numeric nutrient threshold. The narrative criterion in paragraph 62-302.530(47)(b), F.A.C., applies.	No numeric nutrient threshold. The narrative criterion in paragraph 62-302.530(47)(b), F.A.C., applies.

4.3.3 Inland Nutrient Criteria for estuaries with effective criteria

Numeric criteria for estuaries are expressed as either concentration-based estuary interpretations that are open water, area-wide averages or as load per million cubic meters of freshwater inflow that are the total load of that nutrient to the estuary divided by the total volume of freshwater inflow to that estuary. The criteria, set out at 62-302.532(1).

4.3.4 Inland Nutrient Criteria for lakes

Federal water quality criteria for lakes set out at 40 CFR 131.43(c)(1). The criteria are expressed as concentrations of chlorophyll a, total phosphorus, and total nitrogen as follows:

Lake Color and Alkalinity	Chl-a (mg/L)*	TN (mg/L)	TP (mg/L)
Colored Lakes	0.020	1.27	0.05
(Long-term Color > 40 Platinum Cobalt Units)		[1.27-2.23]	[0.05-0.16]

(PCU)			
Clear Lakes, High Alkalinity (Long-term Color $\leq$ 40 PCU and Alkalinity $>$ 20 mg/L CaCO ₃)	0.020	1.05 [1.05-1.91]	0.03 [0.03-0.09]
Clear Lakes, Low Alkalinity (Long-term Color $\leq$ 40 PCU and Alkalinity $\leq$ 20 mg/L CaCO ₃)	0.006	0.51 [0.51-0.93]	0.01 [0.01-0.03]

* For a given waterbody, the annual geometric mean of chlorophyll *a*, TN or TP concentrations shall not exceed the applicable criterion concentration more than once in a three-year period.

4.3.5 Springs Nutrient Criteria

The numeric criteria for spring is 0.35 mg/L of nitrate-nitrite as an annual geometric mean, not to be exceeded more than once in any three year period.

4.4 Dissolved Oxygen Criteria

Numeric criteria for DO are expressed in terms of minimum and daily average concentrations. While FDEP has adopted revised DO criteria for freshwaters, these revisions have not yet been to EPA for review. Therefore, the applicable criterion for Clean Water Act purposes remains subsection 62-302.530(30), F.A.C.

For Class I and Class III freshwaters, subsection 62-302.530(30) provides as follows:

Shall not be less than 5.0 mg/L. Normal daily and seasonal fluctuations above these levels shall be maintained. [FAC 62-302.530 (30)]

For Class III marine waters, subsection 62-302.530(30) provides as follows:

Shall not average less than 5.0 mg/L in a 24-hour period and shall never be less than 4.0 mg/L. Normal daily and seasonal fluctuations above these levels shall be maintained. [FAC 62-302.530 (30)]

4.5 Biochemical Oxygen Demand Criteria:

Biochemical Oxygen Demand (BOD) shall not be increased to exceed values which would cause dissolved oxygen to be depressed below the limit established for each class and, in no case, shall it be great enough to produce nuisance conditions. [FAC 62-302.530 (11)]

4.6 Natural Conditions

In addition to the standards for nutrients, DO, and BOD described above, Florida's standards include provisions that address waterbodies which do not meet the standards due to natural background conditions.

Florida's water quality standards provide a definition of natural background:

"Natural Background" shall mean the condition of waters in the absence of man-induced alterations based on the best scientific information available to the Department. The establishment of natural background for an altered waterbody may be based upon a similar unaltered waterbody or on historical pre-alteration data. [FAC 62-302.200(16)]

Florida's water quality standards also provide that:

Pollution which causes or contributes to new violations of water quality standards or to continuation of existing violations is harmful to the waters of this State and shall not be allowed. Waters having water quality below the criteria established for them shall be protected and enhanced. However, the Department shall not strive to abate natural conditions. [FAC 62-302.300(15)]

5. Water Quality Assessment

WBIDs 3073 (Crabgrass Creek) and 3084 (Jane Green Creek) were listed as not attaining their designated uses on Florida's 1998 303(d) list for DO and nutrients. To determine impairment, an assessment of available data was conducted. The source for current ambient monitoring data for Crabgrass Creek and Jane Green Creek was the IWR data Run 45. The IWR database contains data from various sources within the state of Florida, including the WMDs and counties.

5.1. Water Quality Data

The tables and figures below present the station locations and time series data for DO, total nitrogen, total phosphorus, BOD, and chlorophyll a observations for Crabgrass Creek and Jane Green Creek.

5.1.1. Crabgrass Creek - WBID 3073

Table 2 provides a list of the water quality monitoring stations in the Crabgrass Creek WBID including the date range of the observations and the number of observations. Figure 7 illustrates where the IWR stations are located within the WBID.

Table 1. Water Quality Monitoring Stations for WBID: 3073 Crabgrass Creek

Station	Station Name	First Date	Last Date	No. Obs.

Figure 7. Station Locations for WBID: 3073 Crabgrass Creek

Dissolved Oxygen

There are several factors that affect the concentration of DO in a waterbody. Oxygen can be introduced by wind, diffusion, photosynthesis, and additions of water with higher DO (e.g. from tributaries). DO concentrations are lowered by processes that use up oxygen from the water, such as respiration and decomposition, and by additions of water with lower DO (e.g. swamp or groundwater). Natural DO levels are a function of water temperature, water depth and velocity, and relative contributions of groundwater. Decomposition of organic matter, such as dead plants and animals, also uses up DO.

Figure 8 provides a time series plot for the measured DO concentrations in Crabgrass Creek. There were 5 monitoring stations used in the assessment that included a total of 43 observations of which 24 (55%) fell below the water quality standard of 5 mg/l DO. The minimum value was 0.23 mg/l, the maximum was 8.2 mg/l and the average was 4.319 mg/l.

Figure 8. WBID: 3073 Crabgrass Creek Measured DO

Biochemical Oxygen Demand

BOD is a measure of the amount of oxygen used by bacteria as they stabilize organic matter. Figure 9 provides a time series plot for the measured BOD concentrations in Crabgrass Creek. There were 3 monitoring stations used in the assessment that included a total of 15 observations. The minimum value was 2 mg/l, the maximum was 7.9 mg/l and the average was 2.514 mg/l.

Figure 9. WBID: 3073 Crabgrass Creek Measured BOD

Nutrients

Excessive nutrients in a waterbody can lead to overgrowth of algae and other aquatic plants such as phytoplankton, periphyton and macrophytes. This process can deplete oxygen in the water, adversely affecting aquatic life and potentially restricting recreational uses such as fishing and boating. For the nutrient assessment the monitoring data for total nitrogen, total phosphorus and chlorophyll a are presented. The current standards for nutrients are narrative criteria. The purpose of the nutrient assessment is to present the range, variability and average conditions for the WBID.

Total Nitrogen

Total Nitrogen (TN) is comprised of nitrate (NO₃), nitrite (NO₂), organic nitrogen and ammonia nitrogen (NH₄). Figure 10 provides a time series plot for the measured TN concentrations in Crabgrass Creek. There were 2 monitoring stations used in the assessment that included a total of 19 observations. The minimum value was 0.454 mg/l, the maximum was 1.427 mg/l and the average was 0.889 mg/l.

Figure 10. WBID: 3073 Crabgrass Creek Measured Total Nitrogen

Total Phosphorus

In natural waters, total phosphorus exists in either soluble or particulate forms. Dissolved phosphorus includes inorganic and organic forms, while particulate phosphorus is made up of living and dead plankton, and adsorbed, amorphous, and precipitated forms. Inorganic forms of phosphorus include orthophosphate and polyphosphates, though polyphosphates are unstable and convert to orthophosphate over time. Orthophosphate is both stable and reactive, making it the form most used by plants. Excessive phosphorus can lead to overgrowth of algae and aquatic plants, the decomposition of which uses up oxygen from the water. Figure 11 provides a time series plot for the measured total phosphorus concentrations in Trout Creek. There were 2 monitoring stations used in the assessment that included a total of 19 observations. The minimum value was 0.055 mg/l, the maximum was 0.230 mg/l and the average was 0.105 mg/l.

Figure 11. WBID: 3073 Crabgrass Creek Measured Total Phosphorus

Chlorophyll a

Chlorophyll is the green pigment in plants that allows them to create energy from light. In a water sample, chlorophyll is indicative of the presence of algae, and chlorophyll-*a* is a measure of the active portion of total chlorophyll. Corrected chlorophyll refers to chlorophyll-*a* measurements that are corrected for the presence of pheophytin, a natural degradation product of chlorophyll that can interfere with analysis because it has an absorption peak in the same spectral region.

Figure 12 provides a time series plot for corrected chlorophyll *a* concentrations in Crabgrass Creek. There were 2 monitoring stations used in the assessment that included a total of 19 observations. The minimum value was 1.0 µg/l, the maximum was 11.0 µg/l and the average was 2.45 µg/l.

Figure 13. Station Locations for WBID: 3084 Jane Green Creek

Dissolved Oxygen

There are several factors that affect the concentration of DO in a waterbody. Oxygen can be introduced by wind, diffusion, photosynthesis, and additions of higher DO water (e.g. from tributaries). DO concentrations are lowered by processes that use up oxygen from the water, such as respiration and decomposition, and by additions of water with lower DO (e.g. swamp or groundwater). Natural DO levels are a function of water temperature, water depth and velocity, and relative contributions of groundwater. Decomposition of organic matter, such as dead plants and animals, also uses up DO.

Figure 14 provides a time series plot for the measured DO concentrations in Jane Green Creek. There were 7 monitoring stations used in the assessment that included a total of 123 observations of which 107 (87%) fell below the water quality standard of 5 mg/l DO. The minimum value was 0.28 mg/l, the maximum was 8.79 mg/l and the average was 2.74 mg/l.

Figure 14. WBID: 3084 Jane Green Creek Measured DO

Biochemical Oxygen Demand

BOD is a measure of the amount of oxygen used by bacteria as they stabilize organic matter. Figure 15 provides a time series plot for the measured BOD concentrations in Jane Green Creek. There were 5 monitoring stations used in the assessment that included a total of 19 observations. The minimum value was 2.0 mg/l, the maximum was 3.2 mg/l and the average was 2.08 mg/l.

Figure 15. WBID: 3084 Jane Green Creek Measured BOD

Nutrients

Excessive nutrients in a waterbody can lead to overgrowth of algae and other aquatic plants such as phytoplankton, periphyton and macrophytes. This process can deplete oxygen in the water, adversely affecting aquatic life and potentially restricting recreational uses such as fishing and boating. For the nutrient assessment the monitoring data for total nitrogen, total phosphorus and chlorophyll a are presented. The current standards for nutrients are narrative criteria. The purpose of the nutrient assessment is to present the range, variability and average conditions for the WBID.

Total Nitrogen

Total Nitrogen (TN) is comprised of nitrate (NO₃), nitrite (NO₂), organic nitrogen and ammonia nitrogen (NH₄). Figure 16 provides a time series plot for the measured TN concentrations in Jane Green Creek. There were 7 monitoring stations used in the assessment that included a total of 117 observations. The minimum value was 0.68 mg/l, the maximum was 2.22 mg/l and the average was 1.23 mg/l.

Figure 16. WBID: 3084 Jane Green Creek Measured Total Nitrogen

Total Phosphorus

In natural waters, total phosphorus exists in either soluble or particulate forms. Dissolved phosphorus includes inorganic and organic forms, while particulate phosphorus is made up of living and dead plankton, and adsorbed, amorphous, and precipitated forms. Inorganic forms of phosphorus include orthophosphate and polyphosphates, though polyphosphates are unstable and convert to orthophosphate over time. Orthophosphate is both stable and reactive, making it the form most used by plants. Excessive phosphorus can lead to overgrowth of algae and aquatic plants, the decomposition of which uses up oxygen from the water. Figure 17 provides a time series plot for the measured total phosphorus concentrations in Jane Green Creek. There were 7 monitoring stations used in the assessment that included a total of 106 observations. The minimum value was 0.026 mg/l, the maximum was 0.59 mg/l and the average was 0.11 mg/l.

Figure 17. WBID: 3084 Jane Green Creek Measured Total Phosphorus

Chlorophyll a

Chlorophyll is the green pigment in plants that allows them to create energy from light. In a water sample, chlorophyll is indicative of the presence of algae, and chlorophyll-*a* is a measure of the active portion of total chlorophyll. Corrected chlorophyll refers to chlorophyll-*a* measurements that are corrected for the presence of pheophytin, a natural degradation product of chlorophyll that can interfere with analysis because it has an absorption peak in the same spectral region.

Figure 18 provides a time series plot for corrected chlorophyll *a* concentrations in Jane Green Creek. There were 6 monitoring stations used in the assessment that included a total of 24 observations. The minimum value was 1.00 µg/l, the maximum was 7.1µg/l and the average was 1.98 µg/l.

Figure 18. WBID: 3084 Jane Green Creek Measured Chlorophyll a Concentrations

6. Source and Load Assessment

An important part of the TMDL analysis is the identification of source categories, source subcategories, or individual sources of pollutants in the watershed and the amount of loading contributed by each of these sources. Sources are broadly classified as either point or nonpoint sources. Nutrients can enter surface waters from both point and nonpoint sources.

6.1. Point Sources

A point source is defined as a discernable, confined, and discrete conveyance from which pollutants are or may be discharged to surface waters. Point source discharges of industrial wastewater and treated sanitary wastewater must be authorized by National Pollutant Discharge Elimination System (NPDES) permits. NPDES permitted discharges include continuous discharges such as wastewater treatment facilities as well as some stormwater driven sources such as municipal separate storm sewer systems (MS4s), certain industrial facilities, and construction sites over one acre.

6.1.1. Wastewater/Industrial Permitted Facilities

A TMDL wasteload allocation (WLA) is given to wastewater and industrial NPDES permitted facilities discharging to surface waters within an impaired watershed. There are no NPDES-permitted facilities that discharge within the Crabgrass and Jane Green Creek Watershed.

6.1.2. Stormwater Permitted Facilities/MS4s

MS4s are point sources also regulated by the NPDES program. According to 40 CFR 122.26(b)(8), an MS4 is “a conveyance or system of conveyances (including roads with drainage systems, municipal streets, catch basins, curbs, gutters, ditches, man-made channels, or storm drains):

- (i) Owned or operated by a State, city, town, borough, county, parish, district, association, or other public body (created by or pursuant to State law)...including special districts under State law such as a sewer district, flood control district or drainage district, or similar entity, or an Indian tribe or an authorized Indian tribal organization, or a designated and approved management agency under section 208 of the Clean Water Act that discharges into waters of the United States;
- (ii) Designed or used for collecting or conveying storm water;
- (iii) Which is not a combined sewer; and
- (iv) Which is not part of a Publicly Owned Treatment Works.”

MS4s may discharge nutrients and other pollutants to waterbodies in response to storm events. In 1990, USEPA developed rules establishing Phase I of the NPDES stormwater program, designed to prevent harmful pollutants from being washed by stormwater runoff into MS4s (or from being dumped directly into the MS4) and then discharged from the MS4 into local waterbodies. Phase I of the program required operators of “medium” and “large” MS4s (those generally serving populations of 100,000 or greater) to implement a stormwater management program as a means to control polluted discharges from MS4s. Approved stormwater management programs for medium and large MS4s are required to address a variety of water quality related issues including roadway runoff management, municipal owned operations, hazardous waste treatment, etc.

Phase II of the rule extends coverage of the NPDES stormwater program to certain “small” MS4s. Small MS4s are defined as any MS4 that is not a medium or large MS4 covered by Phase I of the NPDES stormwater program. Only a select subset of small MS4s, referred to as “regulated small MS4s”, requires an NPDES stormwater permit. Regulated small MS4s are defined as all small MS4s located in “urbanized areas” as defined by the Bureau of the Census, and those small MS4s located outside of “urbanized areas” that are designated by NPDES permitting authorities.

In October 2000, USEPA authorized FDEP to implement the NPDES stormwater program in all areas of Florida except Indian tribal lands. FDEP’s authority to administer the NPDES program is set forth in Section 403.0885, Florida Statutes (FS). The three major components of NPDES stormwater regulations are:

- MS4 permits that are issued to entities that own and operate master stormwater systems, primarily local governments. Permittees are required to

implement comprehensive stormwater management programs designed to reduce the discharge of pollutants from the MS4 to the maximum extent practicable.

- Stormwater associated with industrial activities, which is regulated primarily by a multisector general permit that covers various types of industrial facilities. Regulated industrial facilities must obtain NPDES stormwater permit coverage and implement appropriate pollution prevention techniques to reduce contamination of stormwater.
- Construction activity general permits for projects that ultimately disturb one or more acres of land and which require the implementation of stormwater pollution prevention plans to provide for erosion and sediment control during construction.

There are currently no MS4 service areas located within the Crabgrass and Jane Green Creek watershed. Any newly designated MS4s will also be required to achieve the percent reduction allocation presented in this TMDL.

6.2. Nonpoint Sources

Nonpoint sources of pollution are diffuse sources that cannot be identified as entering a waterbody through a discrete conveyance at a single location. For nutrients, these sources include runoff of agricultural fields, golf courses, and lawns, septic tanks, and residential developments outside of MS4 areas. Nonpoint source pollution generally involves a buildup of pollutants on the land surface that wash off during rain events and as such, represent contributions from diffuse sources, rather than from a defined outlet. Potential nonpoint sources are commonly identified, and their loads estimated, based on land cover data. Most methods calculate nonpoint source loadings as the product of the water quality concentration and runoff water volume associated with certain land use practices. The mean concentration of pollutants in the runoff from a storm event is known as the event mean concentration.

Figure 3 provides a map of the land use in the Crabgrass Creek and Jane Green Creek watersheds. Figure 4 provides the landuse distribution for the Crabgrass and Jane Green Watershed. The predominant landuse draining directly to the watershed is agriculture (55%) and wetlands (25%).

The following sections are organized by land use. Each section provides a description of the land use, the typical sources of nutrient loading (if applicable), and typical total nitrogen and total phosphorus event mean concentrations.

6.2.1. Urban Areas

Urban areas include land uses such as residential, industrial, extractive and commercial. Land uses in this category typically have somewhat high total nitrogen event mean concentrations and average total phosphorus event mean concentrations. Nutrient loading from MS4 and

non-MS4 urban areas is attributable to multiple sources including stormwater runoff, leaks and overflows from sanitary sewer systems, illicit discharges of sanitary waste, runoff from improper disposal of waste materials, leaking septic systems, and domestic animals.

In 1982, Florida became the first state in the country to implement statewide regulations to address the issue of nonpoint source pollution by requiring new development and redevelopment to treat stormwater before it is discharged. The Stormwater Rule, as outlined in Chapter 403 FS, was established as a technology-based program that relies upon the implementation of Best Management Practices (BMPs) that are designed to achieve a specific level of treatment (i.e., performance standards) as set forth in Chapter 62-40, FAC.

Florida's stormwater program is unique in having a performance standard for older stormwater systems that were built before the implementation of the Stormwater Rule in 1982. This rule states: "the pollutant loading from older stormwater management systems shall be reduced as needed to restore or maintain the beneficial uses of water." [FAC 62-40-.432(2)(c)]

Nonstructural and structural BMPs are an integral part of the State's stormwater programs. Nonstructural BMPs, often referred to as "source controls", are those that can be used to prevent the generation of nonpoint source pollutants or to limit their transport off-site. Typical nonstructural BMPs include public education, land use management, preservation of wetlands and floodplains, and minimization of impervious surfaces. Technology-based structural BMPs are used to mitigate the increased stormwater peak discharge rate, volume, and pollutant loadings that accompany urbanization.

Urban, residential, and commercial developments are potentially a nonpoint source of nutrients and oxygen-demanding substances in the Crabgrass Creek and Jane Green Creek watersheds. However, landuses in this category comprise less than 1 percent of the watershed area.

Onsite Sewage Treatment and Disposal Systems (Septic Tanks)

As stated above leaking septic tanks or onsite sewage treatment and disposal systems (OSTDs) can contribute to nutrient loading in urban areas. Water from OSTDs is typically released to the ground through on-site, subsurface drain fields or boreholes that allow the water from the tank to percolate (usually into the surficial aquifers) and either transpire to the atmosphere through surface vegetation or add to the flow of shallow ground water. When properly sited, designed, constructed, maintained, and operated, OSTDs are a safe means of disposing of domestic waste. The effluent from a well-functioning OSTD receives natural biological treatment in the soil and is comparable to secondarily treated wastewater from a sewage treatment plant. When not functioning properly, OSTDs can be a source of nutrients, pathogens, and other pollutants to both ground water and surface water.

The State of Florida Department of Health publishes data on new septic tank installations and the number of septic tank repair permits issued for each county in Florida. Table 4 summarizes the cumulative number of septic systems installed since the 1970 census and the

US EPA ARCHIVE DOCUMENT

County	Number of Septic Tanks (1970- 2010)	Number of Repair Permits Issued (1991-2010)
Osceola	24,715	2716

The State of Florida Department of Health also maintains a list of OSTDs that have been inspected by the Florida Department of Health. The purpose for the inspections range from new installations to requested repair work. Figure 19 depicts the OSTDs inspection conducted in and adjacent to WBIDs 3073 and 3084. Without additional information, an explicit source cannot be determined. However, the presence of some OSTDs in close vicinity of both Crabgrass Creek and Jane Green Creek suggests that OSTDs could be potential sources of nutrient and oxygen-demanding substances to the watershed.

Figure 19. OSTDs inspected in the vicinity of Crabgrass Creek and Jane Green Creek

6.2.2. Agriculture

Agricultural lands include improved and unimproved pasture, row and field crops, tree crops, nurseries, and specialty farms. Agricultural activities, including runoff of fertilizers or animal wastes from pasture and cropland and direct animal access to streams, can generate nutrient loading to streams. The highest total nitrogen and total phosphorus event mean concentrations are associated with agricultural land uses.

The USDA National Agricultural Statistics Service (NASS) compiles Census of Agriculture data by county for virtually every facet of U.S. agriculture (USDA NASS, 2007). According to 2007 Census of Agriculture data, there were 181 farms which fertilized approximately 76,782 acres with commercial fertilizer, lime and soil conditioners in Osceola County, Florida. The census also shows that approximately 764 acres of 42 farms were fertilized with manure. Livestock counts of cattle and pigs for Osceola County are provided in Table 5. Because agricultural census data are collected at the county level, the extent to which these values pertain to agricultural fields within the impaired watershed is not specified.

Table 4. 2007 Agricultural Census Data for Livestock in Osceola County, Florida

County	Livestock	Number of Farms	Number of Animals
Osceola	Cattle and Calves	217	102,116
	Hogs and Pigs	21	45

Note: 1. A farm is defined as any place from which \$1,000 or more of agricultural products were produced and sold, or normally would have been sold, during the census year.

Land use data and aerial coverage show that both Crabgrass Creek and Jane Green Creek, and their tributaries, are bordered by agricultural uses (Figure 2). Additionally, agriculture comprises 55 percent of the land use in the Crabgrass and Jane Green Watershed. As such, agricultural uses could be a relevant source of nutrient loading to both of these watersheds.

6.2.3. Rangeland

Rangeland includes herbaceous, scrub, disturbed scrub and coastal scrub areas. Event mean concentrations for rangeland are about average for total nitrogen and low for total phosphorus. Rangeland comprises approximately nine percent of the land use in the watershed.

6.2.4. Upland Forests

Upland forests include flatwoods, oak, various types of hardwoods, conifers and tree plantations. Generally, the pollutant load from wildlife (including both animals and plants) is assumed to represent background concentrations. Event mean concentrations for upland

forests are low for both total nitrogen and total phosphorus. Upland Forests consist of eight percent of the land use in the watershed.

6.2.5. Water and Wetlands

Water and wetlands have very low event mean concentrations down to zero and comprise 25 percent of the land use in the watershed.

6.2.6. Barren Land

Barren land includes beaches, borrow pits, disturbed lands and fill areas. Event mean concentrations for barren lands tend to be higher in total nitrogen. Barren lands comprise less than one percent in the watershed.

6.2.7. Transportation, Communications and Utilities

Transportation uses include airports, roads and railroads. Event mean concentrations for these types of uses are in the mid-range for total nitrogen and total phosphorus. Transportation comprises less than one percent in the watershed.

7. Analytical Approach

In the development of a TMDL there needs to be a method for relating current loadings to the observed water quality problem. This relationship could be: statistical (regression for a cause and effect relationship), empirical (based on observations not necessarily from the waterbody in question) or mechanistic (physically and/or stochastically based) that inherently relate cause and effect using physical and biological relationships.

Two mechanistic models were used in the development of this TMDL. The first model is a dynamic watershed model that predicts the quantity of water and pollutants that are associated with runoff from rain events. The second model is a dynamic water quality model that is capable of integrating the loadings from the watershed model to predict the water quality in the receiving waterbody.

The period of simulation that was considered in the development of this TMDL is January 1, 1997 to January 1, 2010. The models were used to predict time series for total nitrogen, total phosphorus, BOD, dissolved oxygen, and chlorophyll a. The models were calibrated to current conditions and were then used to predict improvements in water quality as function of reductions in loadings.

More details on the model application in the development of the Crabgrass Creek and Jane Green Creek TMDL are presented in Appendix A.

7.1. Loading Simulation Program C++ (LSPC)

LSPC is the Loading Simulation Program in C++, a watershed modeling system that includes streamlined Hydrologic Simulation Program Fortran (HSPF) algorithms for simulating hydrology, sediment, and general water quality overland as well as a simplified stream fate and transport model. LSPC is derived from the Mining Data Analysis System (MDAS), which was originally developed by USEPA Region 3 (under contract with Tetra Tech) and has been widely used for TMDL development. In 2003, the USEPA Region 4 contracted with Tetra Tech to refine, streamline, and produce user documentation for the model for public distribution. LSPC was developed to serve as the primary watershed model for the USEPA TMDL Modeling Toolbox.

LSPC was used to simulate runoff (flow, total nitrogen, total phosphorus and BOD) from the land surface using a daily timestep for current and natural conditions of the Crabgrass Creek and Jane Green Creek watershed. The predicted timeseries were used as boundary conditions for the receiving waterbody model to predict in-stream and in-lake water quality.

7.2. Water Quality Analysis Simulation Program (WASP)

The Water Quality Analysis Simulation Program (WASP) is a dynamic compartment-modeling program for aquatic systems, including both the water column and the underlying benthos. The time-varying processes of advection, dispersion, point and diffuse mass loading and boundary exchange are represented in the basic program. The conventional pollutant model within the WASP framework is capable of predicting time varying concentrations for chlorophyll a, dissolved oxygen, nutrients (nitrogen, phosphorus) as function of loadings, flows, and environmental conditions.

WASP was calibrated to the current conditions of the Crabgrass Creek and Jane Green Creek watershed using known meteorology, predicted loadings from the LSPC model and constrained by observed data in Crabgrass Creek and Jane Green Creek. Furthermore, WASP was used in determining the load reductions that would be needed to achieve the water quality standards and nutrient targets for Crabgrass Creek and Jane Green Creek.

7.3. Scenarios

Several modeling scenarios were developed and evaluated in this TMDL determination. A full description of each of these scenarios is presented in Appendix A.

7.3.1. Current Condition

The first scenario is to model the current conditions of the watershed. This included the development of a watershed and water quality model. The watershed model is parameterized using the current landuses and measured meteorological conditions to predict the current loadings of nitrogen, phosphorus and BOD. These predicted loadings and flow time series are passed on to the water quality model where the predicted algal, nitrogen, phosphorus, BOD and DO concentrations are predicted over time. The models (watershed and water quality) are

calibrated to a thirteen year period of time to take into account varying environmental, meteorological or hydrological conditions on water quality. The existing condition annual average concentrations are presented in Table 6.

Table 5. Existing Condition Annual Average Model Predictions

Constituent	Simulated
BOD (mg/L)	2.33
Chlorophyll a (ug/L)	1.38
DO (mg/L)	1.97
Total Nitrogen (mg/L)	1.09
Total Phosphorus (mg/L)	0.12

The current condition simulation will be used to determine the base loadings for Crabgrass Creek and Jane Green Creek. These base loadings (Table 7) compared with the TMDL scenario will be used to determine the percent reduction in nutrient loads that will be needed to achieve water quality standards.

Table 6. Crabgrass Creek and Jane Green Creek Existing Nutrient Loads (1999-2009)

Constituent	Current Condition	
	WLA (Kg/Yr)	LA (Kg/Yr)
BOD	NA	919,833
Total Nitrogen	NA	379,496
Total Phosphorus	NA	61,073

7.3.2. Natural Condition

The natural condition scenario is developed to estimate what water quality conditions would exist if there were little to no impact from anthropogenic sources. There are no point source dischargers in the Crabgrass Creek and Jane Green Creek watershed. For the purpose of this analysis any landuse that is associated with man induced activities (urban, agriculture, transportation, barren lands and rangeland) is converted to upland forests and wetlands (50/50 split) and the associated event mean concentration for nitrogen, phosphorus and BOD are used. These natural condition loadings from the watershed model are passed onto the water quality model where natural water quality conditions are predicted. The natural condition water quality predictions are presented in Table 8.

Table 7. Natural Condition Annual Average Model Predictions

Constituent	Natural
BOD (mg/L)	1.94
Chlorophyll a (ug/L)	1.37
DO (mg/L)	2.60
Total Nitrogen (mg/L)	0.88
Total Phosphorus (mg/L)	0.09

The purpose of the natural conditions scenario is to determine whether water quality standards can be achieved without abating the naturally occurring loads from the watershed. The DO standard is not achievable under natural conditions. Therefore, the TMDL determination will set the allowable loads to the natural condition scenario.

Table 9 provides the natural condition annual average load predictions for total nitrogen, total phosphorus, and BOD.

Table 8. Natural Condition Annual Average Nutrient

Natural Condition		
Constituent	WLA (kg/yr)	LA (kg/yr)
BOD	NA	716,943
Total Nitrogen	NA	342,682
Total Phosphorus	NA	39,855

Figure 20 provides a time series of DO concentrations under natural conditions. The model predicts 40% exceedances of the DO criteria and the minimum DO concentration is 0.0 mg/L.

Figure 20. DO Concentration Time Series under Natural Condition

Figure 21 provides a comparison of the cumulative distribution function of the DO concentrations under natural and current (existing) conditions.

Figure 21. DO Concentration Cumulative Distribution Function Natural vs. Current Condition

8. TMDL Determination

The TMDL for a given pollutant and waterbody is comprised of the sum of individual WLAs for point sources, and load allocations (LAs) for both nonpoint sources and natural background levels. In addition, the TMDL must include a margin of safety (MOS), either implicitly or explicitly, to account for the uncertainty in the relationship between pollutant loads and the quality of the receiving waterbody. Conceptually, this definition is represented by the equation:

$$\text{TMDL} = \sum \square \text{WLAs} + \sum \square \text{LAs} + \text{MOS}$$

The TMDL is the total amount of pollutant that can be assimilated by the receiving waterbody and still achieve water quality standards and the waterbody's designated use. In TMDL development, allowable loadings from all pollutant sources that cumulatively amount to no more than the TMDL must be set and thereby provide the basis to establish water quality-based controls. These TMDLs are expressed as annual mass loads, since the approach used to determine the TMDL targets relied on annual loadings. The TMDLs targets were determined to be the conditions needed to restore and maintain a balanced aquatic system. Furthermore, it is important to consider nutrient loading over time, since nutrients can accumulate in waterbodies.

During the development of this TMDL, it was determined that the natural condition scenario (removal of all anthropogenic sources and landuses) does not meet the Florida standards for DO. The reductions prescribed in this TMDL reduce the current loadings to the natural condition in order to not abate a natural condition.

The TMDL was determined for the loadings coming from the upstream watershed and watershed that directly drains to Crabgrass Creek and Jane Green Creek. The allocations are given in Table 10.

Table 9. TMDL Load Allocations for WBIDs 3073 and 3084 (Crabgrass Creek and Jane Green Creek)

Constituent	Current Condition		TMDL Condition		MS4	LA
	WLA (kg/yr)	LA (kg/yr)	WLA (kg/yr)	LA (kg/yr)	% Reduction	% Reduction
BOD	NA	919,833	NA	716,943	NA	22%
Total Nitrogen	NA	379,496	NA	342,682	NA	10%
Total Phosphorus	NA	61,073	NA	39,855	NA	35%

8.1. Critical Conditions and Seasonal Variation

EPA regulations at 40 CFR 130.7(c)(1) require TMDLs to take into account critical conditions for stream flow, loading, and water quality parameters. The critical condition is the

combination of environmental factors creating the "worst case" scenario of water quality conditions in the waterbody. By achieving the water quality standards at critical conditions, it is expected that water quality standards should be achieved during all other times. Seasonal variation must also be considered to ensure that water quality standards will be met during all seasons of the year, and that the TMDLs account for any seasonal change in flow or pollutant discharges, and any applicable water quality criteria or designated uses (such as swimming) that are expressed on a seasonal basis.

The critical condition for nonpoint source loadings and wet weather point source loadings is typically an extended dry period followed by a rainfall runoff event. During the dry weather period, nutrients build up on the land surface, and are washed off by rainfall. The critical condition for continuous point source loading typically occurs during periods of low stream flow when dilution is minimized. Although loading of nonpoint source pollutants contributing to a nutrient impairment may occur during a runoff event, the expression of that nutrient impairment is more likely to occur during warmer months, and at times when the waterbody is poorly flushed. Because of the thirteen year simulation period used in the model development, the model encompasses both critical and seasonal variations to determine the annual average allowable load.

8.2. *Margin of Safety*

The MOS accounts for uncertainty in the relationship between a pollutant load and the resultant condition of the waterbody. There are two methods for incorporating an MOS into TMDLs (USEPA, 1991):

- Implicitly incorporate the MOS using conservative model assumptions to develop allocations
- Explicitly specify a portion of the total TMDL as the MOS and use the remainder for allocations

This TMDL uses an implicit MOS since the TMDL targets for nutrients were set to natural background conditions.

8.3. *Waste Load Allocations*

Only MS4s and NPDES facilities discharging directly into lake segments (or upstream tributaries of those segments) are assigned a WLA. The WLAs, if applicable, are expressed separately for continuous discharge facilities (e.g., WWTPs) and MS4 areas, as the former discharges during all weather conditions whereas the later discharges in response to storm events.

8.3.1. *Wastewater/Industrial Permitted Facilities*

There is no continuous discharge NPDES permitted point sources in the Crabgrass Creek and Jane Green Creek watershed; therefore, no WLA was calculated.

8.3.2. Municipal Separate Storm Sewer System Permits

The WLA for MS4s are expressed in terms of percent reductions equivalent to the reductions required for nonpoint sources. Given the available data, it is not possible to estimate loadings coming exclusively from the MS4 areas. Although the aggregate wasteload allocations for stormwater discharges are expressed in numeric form, i.e., percent reduction, based on the information available today, it is infeasible to calculate numeric WLAs for individual stormwater outfalls because discharges from these sources can be highly intermittent, are usually characterized by very high flows occurring over relatively short time intervals, and carry a variety of pollutants whose nature and extent varies according to geography and local land use. For example, municipal sources such as those covered by this TMDL often include numerous individual outfalls spread over large areas. Water quality impacts, in turn, also depend on a wide range of factors, including the magnitude and duration of rainfall events, the time period between events, soil conditions, fraction of land that is impervious to rainfall, other land use activities, and the ratio of stormwater discharge to receiving water flow.

This TMDL assumes for the reasons stated above that it is infeasible to calculate numeric water quality-based effluent limitations for stormwater discharges. Therefore, in the absence of information presented to the permitting authority showing otherwise, this TMDL assumes that water quality-based effluent limitations for stormwater sources of nutrients derived from this TMDL can be expressed in narrative form (e.g., as best management practices), provided that: (1) the permitting authority explains in the permit fact sheet the reasons it expects the chosen BMPs to achieve the aggregate wasteload allocation for these stormwater discharges; and (2) the state will perform ambient water quality monitoring for nutrients for the purpose of determining whether the BMPs in fact are achieving such aggregate wasteload allocation.

All Phase 1 MS4 permits issued in Florida include a re-opener clause allowing permit revisions for implementing TMDLs once they are formally adopted by rule. Florida may designate an area as a regulated Phase II MS4 in accordance with Rule 62-620.800, FAC. Florida's Phase II MS4 Generic Permit has a "self-implementing" provision that requires MS4 permittees to update their stormwater management program as needed to meet their TMDL allocations once those TMDLs are adopted. Permitted MS4s will be responsible for reducing only the loads associated with stormwater outfalls which it owns, manages, or otherwise has responsible control. MS4s are not responsible for reducing other nonpoint source loads within its jurisdiction. There are currently no MS4s permitted within the Crabgrass Creek and Jane Green Creek watershed. All future MS4s permitted in the area are automatically prescribed a WLA equivalent to the percent reduction assigned to the LA.

8.4. Load Allocations

The load allocation for nonpoint sources was assigned a percent reduction in BOD and nutrient loadings from the current loadings coming into Crabgrass Creek and Jane Green Creek (See Table 10).

9. Recommendations/Implementation

This TMDL is based on mechanistic modeling of the dissolved oxygen and eutrophication processes using available meteorologic data, hydrologic data, stream geometry, water chemistry data and the evidence of low reaeration, high detrital loading, strong photosynthetic activity, and strong Sediment Oxygen Demand (SOD). The lack of SOD measurements, reaeration measurements, aquatic macrophyte and periphyton measurements introduces uncertainty into this TMDL. Collection of these additional data will help reduce uncertainty and better assess the contribution of potential sources, the timing of any water quality exceedances, and necessary reductions.

The initial step in implementing a TMDL is to more specifically locate pollutant source(s) in the watershed. FDEP employs the Basin Management Action Plan (B-MAP) as the mechanism for developing strategies to accomplish the specified load reductions. Components of a B-MAP are:

- Allocations among stakeholders
- Listing of specific activities to achieve reductions
- Project initiation and completion timeliness
- Identification of funding opportunities
- Agreements
- Local ordinances
- Local water quality standards and permits
- Follow-up monitoring
